[1] Data for March 1982 have been revised to reflect the availability of late reports and corrections by respondents. All data are subject to revision 4 months after original publication.

[2] Prices for natural gas are lagged 1 month.

[3] Includes only domestic production.

[4] Most prices for refined petroleum products are lagged 1 month.

[5] Some prices for industrial chemicals are lagged 1 month.

r=revised.

23. Producer Price Indexes, for special commodity groupings

[1967 = 100 unless otherwise specified]

Commodity grouping	Annual average 1981	1981						1982						
		July	Aug.	Sept.	Oct.	Nov.	Dec.	Jan.	Feb.	Mar.[1]	Apr.	May	June	July
All commodities — less farm products	295.7	298.0	298.7	298.5	299.5	299.4	300.0	302.0	301.9	301.4	300.9	301.1	302.3	304.1

r = revised.

PRODUCTIVITY DATA

PRODUCTIVITY DATA are compiled by the Bureau of Labor Statistics from establishment data and from estimates of compensation and output supplied by the U.S. Department of Commerce and the Federal Reserve Board.

Definitions

Output is the constant dollar gross domestic product produced in a given period. Indexes of **output per hour of labor input**, or labor productivity, measure the value of goods and services produced per hour of labor. **Compensation per hour** includes wages and salaries of employees plus employers' contributions for social insurance and private benefit plans. The data also include an estimate of wages, salaries, and supplementary payments for the self-employed, except for nonfinancial corporations, in which there are no self-employed. **Real compensation per hour** is compensation per hour adjusted by the Consumer Price Index for All Urban Consumers.

Unit labor cost measures the labor compensation cost required to produce one unit of output and is derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from the current dollar gross domestic product and dividing by output. In these tables, **unit nonlabor costs** contain all the components of unit nonlabor payments except unit profits. **Unit profits** include corporate profits and inventory valuation adjustments per unit of output.

The **implicit price deflator** is derived by dividing the current dollar estimate of gross product by the constant dollar estimate, making the deflator, in effect, a price index for gross product of the sector reported.

The use of the term "man hours" to identify the labor component of productivity and costs, in tables 26 through 29, has been discontinued. **Hours of all persons** is now used to describe the labor input of payroll workers, self-employed persons, and unpaid family workers. **Output per all-employee hour** is now used to describe labor productivity in nonfinancial corporations where there are no self-employed.

Notes on the data

In the business sector and the nonfarm business sector, the basis for the output measure employed in the computation of output per hour is Gross Domestic Product rather than Gross National Product. Computation of hours includes estimates of nonfarm and farm proprietor hours.

Output data are supplied by the Bureau of Economic Analysis, U.S. Department of Commerce, and the Federal Reserve Board. Quarterly manufacturing output indexes are adjusted by the Bureau of Labor Statistics to annual estimates of output (gross product originating) from the Bureau of Economic Analysis. Compensation and hours data are from the Bureau of Economic Analysis and the Bureau of Labor Statistics.

Beginning with the September 1982 issue of the *Review*, all of the productivity and cost measures contained in these tables are based on revised output and compensation measures released by the Bureau of Economic Analysis in July as part of the regular revision cycle of the National Income and Product Accounts. Measures of labor input have been revised to reflect results of the 1980 census, and seasonal factors have been recomputed for use in the preparation of quarterly measures. The word "private" will no longer be used as part of the series title of one of the two business sector measures prepared by BLS; no change has been made in the definition or content of the measures as a result of this change.

WAGE AND COMPENSATION DATA

Data for the Employment Cost Index are reported to the Bureau of Labor Statistics by a sample of 2,000 private nonfarm establishments and 750 State and local government units selected to represent total employment in those sectors. On average, each reporting unit provides wage and compensation information on five well-specified occupations.

Data on negotiated wage and benefit changes are obtained from contracts on file at the Bureau, direct contact with the parties, and secondary sources.

Definitions

The **Employment Cost Index** (ECI) is a quarterly measure of the average change in the cost of employing labor. The rate of total compensation, which comprises wages, salaries, and employer costs for employee benefits, is collected for workers performing specified tasks. Employment in each occupation is held constant over time for all series produced in the ECI, except those by region, bargaining status, and area. As a consequence, only changes in compensation are measured. Industry and occupational employment data from the 1970 Census of Population are used in deriving constant weights for the ECI. While holding total industry and occupational employment fixed, in the estimation of indexes by region, bargaining status, and area, the employment in those measures is allowed to vary over time in accord with changes in the sample. The rate of change (in percent) is available for wages and salaries, as well as for total compensation. Data are collected for the pay period including the 12th day of the survey months of March, June, September, and December. The statistics are neither annualized nor adjusted for seasonal influence.

Wages and salaries consist of earnings before payroll deductions, excluding premium pay for overtime, work on weekends and holidays, and shift differentials. Production bonuses, incentive earnings, commissions, and cost-of-living adjustments are included; nonproduction bonuses are included with other supplemental pay items in the benefits category; and payments-in-kind, free room and board, and tips are excluded. *Benefits* include supplemental pay, insurance, retirement and savings plans, and hours-related and legally required benefits.

Data on negotiated wage changes apply to private nonfarm industry collective bargaining agreements covering 1,000 workers or more. Data on compensation changes apply only to those agreements covering 3,000 workers or more. *First-year* wage or compensation changes refer to average negotiated changes for workers covered by settlements reached in the period and implemented within the first 12 months after the effective date of the agreement. *Changes over the life of the agreement* refer to all adjustments specified in the contract, expressed as an average annual rate. These measures exclude wage changes that may occur under cost-of-living adjustment clauses, that are triggered by movements in the Consumer Price Index. *Wage-rate changes* are expressed as a percent of straight-time hourly earnings; *compensation changes* are expressed as a percent of total wages and benefits.

Effective wage adjustments reflect all negotiated changes implemented in the reference period, regardless of the settlement date. They include changes from settlements reached during the period, changes deferred from contracts negotiated in an earlier period, and cost-of-living adjustments. The data also reflect contracts providing for no wage adjustment in the period. Effective adjustments and each of their components are prorated over all workers in bargaining units with at least 1,000 workers.

Notes on the data

The Employment Cost Index data series began in the fourth quarter of 1975, with the quarterly percent change in wages and salaries in the private nonfarm sector. Data on employer costs for employee benefits were included in 1980, to produce a measure of the percent change in employers' cost for employees' total compensation. State and local government units were added to the ECI coverage in 1981, providing a measure of total compensation change in the civilian nonfarm economy.

Data for the broad white-collar, blue-collar, and service worker groups, and the manufacturing, nonmanufacturing, and service industry groups are presented in the ECI. Additional occupation and industry detail are provided for the wages and salaries component of total compensation in the private nonfarm sector. For State and local government units, additional industry detail is shown for both total compensation and its wages and salaries component.

Historical indexes (June 1981 = 100) of the quarterly rates of changes presented in the ECI are also available.

For a more detailed discussion of the ECI, see chapter 25, "The Employment Cost Index," of the BLS *Handbook of Methods* (Bulletin 1910), and the *Monthly Labor Review* articles: "Employment Cost Index: a measure of change in the 'price of labor,'" July 1975; "How benefits will be incorporated into the Employment Cost Index," January 1978; and "The Employment Cost Index: recent trends and expansion," May 1982.

Additional data for the ECI and other measures of wage and compensation changes appear in *Current Wage Developments*, a monthly periodical of the Bureau.

r=revised.

34. Effective wage adjustments in collective bargaining units covering 1,000 workers or more, 1977 to date

Measure	Year					Year and quarter								
						1980			1981				1982^{p}	
	1977	1978	1979	1980	1981	II	III	IV	I	II	III	IV	I^{r}	II
Average percent adjustment (including no change):														
All industries	8.0	8.2	9.1	9.9	9.5	3.3	3.5	1.3	1.7	3.2	3.3	1.5	1.0	1.9
Manufacturing	8.4	8.6	9.6	10.2	9.4	3.4	2.9	1.7	2.3	2.4	3.1	1.9	.9	.9
Nonmanufacturing	7.6	7.9	8.8	9.7	9.5	3.2	4.0	1.1	1.2	3.8	3.4	1.1	1.0	2.6
From settlements reached in period	3.0	2.0	3.0	3.6	2.5	1.0	1.7	.5	.4	1.1	.5	.4	.2	.3
Deferred from settlements reached in earlier period	3.2	3.7	3.0	3.5	3.8	1.4	1.2	.3	.5	1.4	1.5	.4	.6	1.3
From cost-of-living clauses	1.7	2.4	3.1	2.8	3.2	.8	.7	.6	.7	.7	1.2	.6	.3	.2
Total number of workers receiving wage change (in thousands)[1]	—	—	—	—	8,648	—	—	—	3,655	4,701	4,364	3,225	2,955	3,359
From settlements reached in period	—	—	—	—	2,270	—	—	—	579	909	540	604	190	407
Deferred from settlements reached in earlier period	—	—	—	—	6,267	—	—	—	866	2,055	3,023	882	1,038	1,629
From cost-of-living clauses	—	—	—	—	4,593	—	—	—	2,630	2,660	2,934	2,179	1,980	1,496
Number of workers receiving no adjustments (in thousands)	—	—	—	—	145	—	—	—	4,937	4,092	4,426	5,568	5,767	5,264

[1] The total number of workers who received adjustments does not equal the sum of workers that received each type of adjustment, because some workers received more than one type of adjustment during the period.

r=revised.

WORK STOPPAGE DATA

Work stoppages include all known strikes or lockouts involving 1,000 workers or more and lasting a full shift or longer. Data are based largely on newspaper accounts and cover all workers idle one shift or more in establishments directly involved in a stoppage. They do not measure the indirect or secondary effect on other establishments whose employees are idle owing to material or service shortages.

Estimates of days idle as a percent of estimated working time measures only the impact of larger strikes (1,000 workers or more). Formerly, these estimates measured the impact of strikes involving 6 workers or more; that is, the impact of virtually *all* strikes. Due to budget stringencies, collection of data on strikes involving 6 workers or more was discontinued with the December 1981 data.

35. Work stoppages involving 1,000 workers or more, 1947 to date

Month and year		Number of stoppages		Workers involved		Days idle	
		Beginning in month or year	In effect during month or year	Beginning in month or year (in thousands)	In effect during month (in thousands)	Number (in thousands)	Percent of estimated working time

Published by BLS in July

SALES PUBLICATIONS

BLS Bulletins

Handbook of Labor Statistics. Bulletin 2070 (reissued), 489 pp., $15 (GPO Stock No. 029-001-02542-4). Makes available in one volume historical data (through 1979 in most cases) on the major statistical series produced by BLS. Also includes related series from other Government agencies and foreign countries.

Rent or Buy? Evaluating Alternatives in the Shelter Market. Bulletin 2016, 21 pages plus a new 3-page supplement, $3.50 (GPO Stock No. 029-001-02309-0). Provides a step-by-step procedure to compare the financial aspects of owning versus renting. (Available only from the Superintendent of Documents.)

Area Wage Survey Bulletins

These bulletins cover office, professional, technical, maintenance, custodial, and material movement occupations in major metropolitan areas.

The annual series of 70 publications is available by subscription for $90 per year. Individual area bulletins are also available separately.

Atlanta, Georgia, Metropolitan Area, May 1982. Bulletin 3015-17, 40 pp., $4.50 (GPO Stock No. 029-001-90136-4).

Houston, Texas, Metropolitan Area, May 1982. Bulletin 3015-20, 40 pp., $4.50 (GPO Stock No. 029-001-90139-9).

Milwaukee, Wisconsin, Metropolitan Area, May 1982. Bulletin 3015-18, 42 pp., $4.50 (GPO Stock No. 029-001-90137-2).

San Antonio, Texas, Metropolitan Area, May 1982. Bulletin 3015-19, 28 pp., $3.50 (GPO Stock No. 029-001-90138-1).

Toledo, Ohio—Michigan, Metropolitan Area, June 1982. Bulletin 3015-21, 30 pp., $3.75 (GPO Stock No. 0290-001-90140-2).

Worcester, Massachusetts, Metropolitan Area, April 1982. Bulletin 3015-16, 27 pp., $3.50 (GPO Stock No. 029-001-90135-0).

Industry Wage Survey Bulletins

These studies include results from the latest BLS survey of wages and supplemental benefits, with detailed occupational data for the Nation, regions, and selected areas (where available). Data are useful for wage and salary administration, union contract negotiation, arbitration, and Government policy considerations.

Certificated Air Carriers, September 1980. Bulletin 2129, 33 pp., $4.50 (GPO Stock No. 029-001-02710-9).

Cigarette Manufacturing, June 1981. Bulletin 2132, 12 pp., $3 (GPO Stock No. 029-001-02708-7).

Men's and Boys' Shirts and Nightwear, May 1981. Bulletin 2131, 58 pp., $5 (GPO Stock No. 029-001-02709-5).

Periodicals

CPI Detailed Report, May. Comprehensive report on consumer price movements, including statistical tables and technical notes. 81 pp., $3.50 ($20 per year).

Employment and Earnings, July. Report on national, State, and area employment; unemployment; hourly and weekly earnings; and hours of work for June. 155 pp., $3.75 ($31 per year).

Producer Prices and Price Indexes, Data for May 1982. Monthly report on producer price movements. Text, tables, and technical notes. 114 pp., $3.25 ($20 per year).

Mailgram Service

Consumer price index data summary by mailgram within 24 hours of the CPI release. Provides unadjusted and seasonally adjusted U.S. City Average Data for All Urban Consumers (CPI-U) and for Urban Wage Earners and Clerical Workers, (CPI-W). (NTISUB/158). $125 in contiguous United States.

MONTHLY LABOR REVIEW

OCTOBER 1982
VOLUME 105, NUMBER 10

Henry Lowenstern, Editor-in-Chief
Robert W. Fisher, Executive Editor

Patricia A. Daly 3 **Unpaid family workers: long-term decline continues**
The number of those working without pay in family businesses in 1981 was less than half the total recorded in 1950, the sharpest drop occurring in the agricultural sector

A. S. Herman, J. W. Ferris 6 **Productivity growth average in farm machinery manufacturing**
Productivity gains, aided by new technology, especially computers, but moderated by cyclical downturns, averaged 2.6 percent a year during the 1958–80 period

M. K. Farris, J. D. York 11 **Hand and edge tool industry experiences slow rise in productivity**
During 1958–80, annual productivity growth averaged just 1.3 percent, less than half the rate of manufacturing as a whole; industry employment grew by more than 50 percent

Paul S. Adler 15 **The productivity puzzle: numbers alone won't solve it**
From managament, labor, academia, and government, contributors to four recent books grapple with the lag in productivity growth, with little help from economic theory

Helen Ginsburg 22 **Sweden combats unemployment of young and older workers**
Joblessness among the 16- to 24-year-olds and those 45 years and over in Sweden, although low by American standards, worsened during the recessions of the 1970's

REPORTS

Labor Month In Review

COOPERATION between management and labor was the focus of an unusual conference that drew nearly 1,000 industrial relations practitioners to Washington, D.C., September 9 and 10. Sponsored by the Federal Mediation and Conciliation Service, the conference featured a report by Peter Pestillo, vice president for labor relations of the Ford Motor Company, about union-management cooperation in the auto industry, and a score of discussions and workshop sessions dealing with labor-management committees, quality of worklife programs, quality circles, and similar efforts. Excerpts:

Daniel Quinn Mills, Harvard University: Collective bargaining practiced primarily as rule-making has become self-defeating for both unions and management. We must go beyond both rule-making and the adversarial emphasis if a major new contribution to American economic performance is to be made. Rule-making may be replaced by a greater degree of employee participation and commitment in the workplace, but unless the adversarial posture changes, increased participation is of no use. Instead of resolving production problems, participatory schemes will simply add additional delays to management decisionmaking.

It is time to draw on the older tradition of the American labor movement to move beyond the concept of collective bargaining as primarily a rule-making process. This should be done by putting far more flexibility into the collective bargaining agreement through less detailed provisions, through reorganized work arrangements, and through different incentives for both management and labor. Some rule-making and the legal enforceability of contracts are not to be abandoned. But they must now take a back seat to attempts to move the collective bargaining process beyond continual confrontation and into a more constructive mode.

A commitment to enhancing productivity is not easily made by American unionists. Too often increased productivity has simply meant speeding up the pace at which managers require employees to work. But there is far more to improving productivity than speedups; and the failure to seek productivity improvement in a company threatens the continued existence of jobs that the company provides. Unions must find a way to be more sophisticated in their response to management efforts to improve productivity. Some efforts should be opposed, but others must be supported. And the goal of improving productivity should be accepted.

Raymond J. Donovan, Secretary of Labor: I recently created, within the Department's Labor-Management Services Administration, a Division of Cooperative Labor-Management programs. This new unit, whose work is just now getting under way, will serve as the focal point of our various activities in this area of concern. It will be responsible for developing and administering a program of technical assistance and information designed to encourage and assist employers and unions to undertake joint efforts to enlist the talents and energies of workers in a common campaign to improve productivity and quality of working life. When fully operative, management and union officials, as well as academic and other third parties, should have at their disposal a hitherto unavailable store of information about current issues and innovative industrial relations practices. While these kinds of data may now exist in goodly amounts, they are widely scattered and not readily accessed by those most in need of them. As a result of this information clutter, there is too much reinventing of the wheel and too little chance to build on the basis of experience already gained. The type of central information exchange we envision should go far to correct this problem.

One of the chief purposes of the Labor Department's program is to bolster existing institutional capabilities by providing services primarily to such intermediate support groups as area and industry labor-management committees, productivity and quality of working life centers, trade associations and international unions. These are the organizations that local employers and unions should rely on to obtain more direct forms of assistance in developing their own cooperative programs.

Glenn Watts, president, Communications Workers of America: During the past few years, Quality of Work Life has become a controversial topic for American labor. A growing number of unions have become involved in QWL efforts, either on their own initiative or management's; but at the same time opposition has become stronger.

The controversy comes from the fact that QWL challenges many of the traditional ways in which unions do business. It is based, first of all, on a cooperative, problem-solving relationship between labor and management, instead of the familiar adversarial style.

One result is that in most QWL efforts the grievance rate drops significantly. And further, QWL increases the direct contact between employers and shop-floor workers, threatening to bypass the union.

These aspects of QWL are seen by many in the labor movement as a threat. But others—and I include myself among them—see it as offering a great opportunity to extend the reach of collective bargaining. □

Unpaid family workers: long-term decline continues

The number of those working without pay in family businesses dropped by 1981 to less than half of the 1950 total; agriculture, where most had been employed, registered the sharpest loss of jobs

PATRICIA A. DALY

For more than 30 years, the total number of persons working without pay in family businesses has dwindled to a point that, by 1981, was less than half of the 1950 total. At 650,000, unpaid family workers accounted for less than 1 percent of total employment in 1981, down from almost 3 percent in 1950.

Historically, the vast majority of unpaid family workers had been in the agricultural sector, but there are now fewer unpaid family workers in agriculture than in other industries. Unpaid family workers accounted for one-sixth of farm employment in 1950, but for less than one-tenth in 1981. The largest numerical decline occurred between 1960 and 1970, a decade which experienced dramatic declines in total agricultural employment. Although the number of unpaid family workers in nonagricultural industries has fluctuated in the last 30 years, the levels for 1950 and 1981 were virtually the same at about 400,000, a very small share of nonfarm employment. (See table 1.)

This article is the first by the Bureau of Labor Statistics to examine and analyze the available data on unpaid family workers. The group, although numerically small, exhibits some interesting characteristics and reflects some of the widespread changes in the work force and the economy.

Classification of workers

Since the 1940's, the Current Population Survey (a monthly survey of households) has obtained information on an individual's labor force activity during a designated period. Based on the responses of a household member to a series of questions, each individual aged 16 years and older is classified as employed, unemployed, or not in the labor force. To be considered employed, a person must be paid for at least one hour of work (wage and salary worker); operate one's own business, profession, or farm (self-employed); or work without pay for 15 or more hours per week in a family business or on a family farm (unpaid family worker). Those who have a job but are not at work temporarily for such reasons as illness, vacation, or an industrial dispute are also counted as employed, whether or not they are paid.

The first question asked the respondent about each appropriate household member is, "What was . . . doing most of last week—working or something else?" This is followed by "Did . . . do any work at all last week, not counting work around the house?" If there is already a farm or business operator enumerated in the household, the respondent is asked specifically about unpaid work.

Data are collected on hours worked at all jobs; however, an individual is assigned to an occupation, industry, and class-of-worker category based on the job in which he or she worked the most hours. Thus, individu-

Table 1. Unpaid family workers in agriculture and nonagricultural industries by sex, annual averages, selected years, 1950–81

[Numbers in thousands]

Industry and year	Total		Men		Women	
	Number	Percent of employment	Number	Percent of employment	Number	Percent of employment
All industries:						
1950 . . .	1,573	2.7	523	1.3	1,050	6.1
1960 . . .	1,499	2.3	385	.9	1,114	5.1
1970 . . .	1,001	1.3	213	.4	788	2.7
1981 . . .	656	.7	138	.2	519	1.2
Agriculture:						
1950 . . .	1,190	16.6	466	7.8	724	62.5
1960 . . .	901	16.5	310	6.9	596	60.4
1970 . . .	499	14.4	160	5.6	339	56.4
1981 . . .	266	7.9	91	3.4	176	26.4
Nonagriculture:						
1950 . . .	383	.7	57	.2	326	2.0
1960 . . .	598	1.0	75	.2	518	2.5
1970 . . .	502	.7	53	.1	449	2.2
1981 . . .	390	.4	47	.1	343	.8

als who do unpaid family work but work more hours in another job are not counted as unpaid family workers.

Demographic changes

Sex. Women are far more likely to be unpaid family workers than men, particularly in nonagricultural industries. As the mix between agriculture and nonagricultural industries has changed, the female proportion of unpaid family workers has increased:

	1950	*196*	*1970*	*1981*
Total employment (in percent):				
Men	30	26	21	21
Women	70	74	79	79
Agriculture:				
Men	35	34	32	34
Women	65	66	68	66
Nonagriculture:				
Men	15	13	11	12
Women	85	87	89	88

The number of unpaid female family workers declined by 530,000 between 1950 and 1981 and the number of male workers, by 300,000. The percentage declines were more drastic for men overall (74 percent) than for women (51 percent). Table 1 provides employment levels and the percent of agriculture and nonagricultural employment which unpaid family work represents.

The employment declines may reflect changing societal values and economic conditions which include the fact that more women are seeking paid employment and that there is an increasing societal acceptance and expectation of this phenomenon. In agriculture, particularly, the trends are consistent with the breakup of the traditional family farm which has resulted in increases in farm size, decreases in the number of farms, more incorporations, and more part-time farming.

Age. One of the ways in which young persons can gain valuable experience and assist their families until they begin their own careers is by doing unpaid family work. As the following percentage distribution of 1981 data suggests, the vast majority of male unpaid family workers are under 25 years of age, while most women in this category are in the central age group—25 to 54:

	Agriculture		*Nonagriculture*	
	Men	*Women*	*Men*	*Women*
Total number (in thousands) . .	91	176	47	343
Percent	100	100	100	100
Ages 16–24 . .	81	13	57	7
Ages 25–54 . .	11	67	23	73
Ages 55 and over	8	20	19	20

The large differential may reflect the fact that men in the central age group were somewhat more likely to seek paid employment. What may be more important, however, is that, in a family operated business or farm, the husband may be counted as self-employed and the wife as an unpaid family worker. This would explain the large percentage of female unpaid family workers in the 25–54 age group. The fact that men accounted for almost 90 percent of the self-employed in agriculture and nearly 70 percent in nonagricultural industries lends some support to this interpretation.

Race. Although black and other minority races made up about 13 percent of the civilian labor force, they accounted for only 2 percent of unpaid family workers in agricultural industries and 6 percent of those in nonagricultural industries. This is undoubtedly related to the low proportion of blacks and other minorities operating their own farms and businesses—4 percent of self-employed workers in agriculture and 7 percent in other industries.

Occupational trends

An examination of data on unpaid family workers by occupation revealed sharp differences between men and women as well as a shift from farm to white-collar occupations as the most common job categories for unpaid family workers. Women accounted for almost 80 percent of unpaid family workers in 1981 and they had more jobs than men in every occupational group. More than half were doing white-collar work, while most of the male unpaid family workers were in farming.

With the decline in unpaid family work on farms, white-collar occupations have overtaken farm occupations as the dominant group for unpaid family workers. Within the white-collar group, three-fourths of unpaid family workers had clerical jobs in 1981 and more than 100,000 were bookkeepers. Unpaid family workers were also frequently employed as secretaries and as sales clerks in retail trade. Individuals doing unpaid family work were dispersed throughout other white-collar occupations, and a sprinkling may be found in blue-collar and service occupations.

The number of farm laborers declined by half a million between 1960 and 1970 and by a quarter million since 1970. Nevertheless, at 254,000 in 1981, farm laborers ranked the highest among the specific occupations.

The nature of various occupations obviously makes them more or less suitable for unpaid family work. It is more likely that a family member will be called upon to do farm chores or typing than plumbing or carpentry.

Patterns by industry

In general, there was a higher incidence of unpaid family workers in industries with a large number of self-employed workers. Agriculture, for instance, had an extremely high percentage of self-employed workers (almost half), and thus had the largest percentage and number of unpaid family workers.

Trade also had a substantial number of unpaid family workers—about 170,000 in 1981 or one-fourth of all unpaid family workers. Most unpaid family workers were in retail trade, with particularly high concentrations in eating and drinking places, groceries, and gasoline service stations—establishments which had a high number of self-employed workers.

Among the service industries, business and repair services such as automobile repair, personal services such as laundry and cleaning, and professional services such as those of physicians and dentists employed more unpaid family workers than others. The self-employed were also well represented in these industries.

Between 1970 and 1981, the greatest industrial change among unpaid family workers was the decline in agricultural employment as its proportion of the total dropped from 50 to 41 percent, representing a reduction of over 200,000 workers. The construction, manufacturing, and miscellaneous service industries all gained in the percentage of unpaid family workers, although only construction and manufacturing actually added jobs.

Hours worked

Unpaid family workers who put in less than 15 hours a week on the job are classified as not in the labor force rather than as employed.[1] In 1981, there were 130,000 persons in this group—mostly women in nonagricultural jobs.

Although obtaining information on the number of hours worked is important, it may be difficult to remember exactly how many hours were worked if no pay was involved. Reporting by another household member (proxy response) may be even less reliable. Nonetheless, it is worthwhile to compare average hours at work for agricultural and nonagricultural workers by whether they work for wages or salary, or are self-employed, or are unpaid family workers:

	Agriculture	*Nonagriculture*
Wage and salary	40.8	37.7
Self-employed	49.3	40.5
Unpaid family workers ..	39.4	35.8

While unpaid family workers averaged fewer hours than either wage and salary or self-employed workers, the differential was not as large as might be anticipated. Thus, in terms of worker input as measured by time, unpaid family work is not a marginal form of employment but rather a significant contribution to family businesses.

THE ECONOMIC STRUCTURE and labor force trends in recent years would seem to preclude the possibility of an increase in either the number or concentration of unpaid family workers in the foreseeable future. If employment in agriculture continues to decline, unpaid family workers will undoubtedly do the same. This tendency is compounded as farms grow larger, incorporate, and consequently employ more wage and salary workers. Because unpaid family work accounts for less than 1 percent of total employment, the aggregate changes are not of great importance. The real significance is the socioeconomic changes which influence a person to choose this kind of work. □

——*FOOTNOTE*——

[1] The number of hours worked is integral to the assignment of a worker to the unpaid family worker category, in that the individual must work 15 or more hours per week to be counted in this group.

Productivity growth average in farm machinery manufacturing

Productivity gains, aided by new technology, especially computers, but moderated by cyclical downturns, averaged 2.6 percent a year over the 1958–80 period

ARTHUR S. HERMAN AND JOHN W. FERRIS

Productivity, as measured by output per employee hour, in farm machinery manufacturing[1] was about the same as the average for all manufacturing industries over the 1958–80 period. Growth was aided by numerically controlled machine tools, automatic welding, computerized manufacturing, industrial robots, and computerized automatic warehouses, but was partially offset by sharp declines in demand. Almost every decline in productivity during the period studied can be associated with a drop in output, which, in turn, usually coincides with downturns in the economy. During the 22-year period, productivity in the farm machinery industry grew at a rate of 2.6 percent a year, compared with 2.7 percent per year for all manufacturing industries; 1.9 percent for construction machinery, an industry which uses similar manufacturing techniques; and 3.2 percent for motor vehicles, another similar industry.

Output, productivity follow farm income

Productivity growth in the farm machinery industry can be divided into three distinct periods. From 1958–65, productivity grew at an annual rate of 1.7 percent; from 1965–74, it accelerated to a 3.3-percent rate; and from 1974–80, slowed to 0.2 percent. (See table 1.) The higher rate of gain during the 1965–74 period can be associated with years of very high output, fueled by dramatic increases in farm income.

Productivity changes in the farm machinery industry are closely tied to output changes over the short term. Demand for farm machinery is based on a number of interrelated factors. A major factor is the overall state of the economy. However, an even more directly related factor is farm income. Changes in the output of farm machinery closely parallel changes in farm income. When farm income is up, farmers tend to purchase new equipment. Among the determinants of income are crop size, both actual and anticipated in the near future, and farm prices. Crop size is, of course, affected by a number of variables, including the weather, farm prices, government policies, and the worldwide food supply. Other important factors affecting the production of farm machinery are farmers' costs, such as for loans, new machinery, land, fertilizers, and pesticides, as well as age and condition of existing equipment and imports and exports of farm equipment.

When income is low and prospects appear poor, farmers tend to make do by repairing, rather than replacing, existing equipment. Conversely, when income is growing and prospects for further expansion of profits appear good, they tend to purchase new, more productive equipment. Demand for machinery increases significantly during these expansive periods, as does productivity.

The impact of the numerous variables affecting demand changes rapidly over time; therefore, output of farm machinery shows wide swings. Productivity, however, moves in a less volatile manner. For example, output grew by 6.3 percent between 1958 and 1959, but

---

Arthur S. Herman is an economist and John W. Ferris is a statistician in the Division of Industry Productivity Studies, Bureau of Labor Statistics.

then dropped precipitously in 1960, a recession year, falling 18.3 percent. Concomitantly, productivity had no growth in 1959 and dropped sharply, by 7.1 percent, in 1960. In 1966, output increased substantially, up 19.4 percent, then declined for 4 consecutive years, one of which was the recession year of 1970. Following output, productivity also grew substantially in 1966, up 6.2 percent, and then dropped sharply, averaging 0.8 percent from 1967 to 1970.

The early 1970's were a period of high output growth, with gains of 16.5 percent in 1972, 21.3 percent in 1973, and 14.3 percent in 1974. This strong growth can be attributed to a sharp increase in farm income resulting, in part, from large exports of farm products, including sales of grain to Russia. Productivity recorded its largest advances during this period, with increases of 8.9 percent in 1971, 9.3 percent in 1972, 5.2 percent in 1973, and 3.6 percent in 1974.

In the more recent period—1980, a recession year—output dropped 15.1 percent, as farm income declined precipitously. In turn, productivity declined 6.7 percent.

A factor affecting output over the long term is the continuously increasing size of farms. The average farm in the United States has shown a significant increase in size, growing about 40 percent in acreage over the period studied.[2] This created a need for an increase in the physical dimensions and horsepower of farm machinery. To cope with the growing acreage, farmers purchased larger, more powerful equipment, rather than increasing their labor force. For example, the average horsepower (PTO) rating of tractors was 106 in 1980, compared with 67 in 1958. Demand for farm equipment has also been enhanced by such equipment as 4-wheel drive tractors, which allow farming in previously marginal areas, and such amenities as air conditioning and stereo radio and cassette equipment in the cabs of the larger units.

Demand for larger, more productive farm machinery has been one factor leading to the industry's long-term growth rate in output of 4.2 percent, somewhat higher than the 3.8 percent for the total manufacturing sector. Highly advanced farm equipment is one of many reasons that productivity has been significantly higher in the farm sector than in the nonfarm sector.

Plants located in Farm Belt

The farm machinery manufacturing industry has paralleled the growth of agriculture in the United States. Some of the larger firms can trace their origins to the development of horse drawn harvesting equipment in the early 1800's. Therefore, farm machinery manufacturing is a mature industry, producing a variety of equipment for both U.S. markets and export.

There were 2,148 establishments in the farm machinery industry as of 1977, a significant increase over the 1,949 establishments reported in 1958. The number of employees per establishment has remained fairly constant, dropping slightly from 74 in 1958 to 70 in 1977 (the average for all manufacturing industries was 53).

Table 1. Output per employee hour and related indexes in the farm machinery equipment industry, 1958–80

[1977=100]

Year	Output per hour			Output	Employee hours		
	All employees	Production workers	Nonproduction workers		All employees	Production workers	Nonproduction workers
1958 . . .	65.1	64.9	65.5	49.4	75.9	76.1	75.4
1959 . . .	65.1	63.4	70.3	52.5	80.7	82.8	74.7
1960 . . .	60.5	61.3	58.8	42.9	70.9	70.0	73.2
1961 . . .	62.9	61.3	67.7	45.7	72.7	74.5	67.5
1962 . . .	65.1	65.1	64.8	48.8	75.0	75.0	75.3
1963 . . .	66.6	64.3	74.3	53.7	80.6	83.5	72.3
1964 . . .	70.2	66.9	82.0	60.1	85.6	89.9	73.3
1965 . . .	72.2	68.6	84.8	64.0	88.6	93.3	75.5
1966 . . .	76.7	72.3	92.7	76.4	99.6	105.6	82.4
1967 . . .	76.8	73.3	86.8	73.6	95.8	100.4	82.9
1968 . . .	76.7	75.0	82.1	70.8	92.3	94.4	86.2
1969 . . .	73.8	73.2	75.9	65.8	89.1	89.9	86.7
1970 . . .	75.7	75.2	77.3	65.1	86.0	86.6	84.2
1971 . . .	82.4	83.0	81.0	66.2	80.3	79.8	81.7
1972 . . .	90.1	87.0	99.9	77.1	85.6	88.6	77.2
1973 . . .	94.8	90.7	109.2	93.5	98.6	103.1	85.6
1974 . . .	98.2	92.6	118.3	106.9	108.9	115.4	90.4
1975 . . .	97.7	95.3	105.2	100.0	102.4	104.9	95.1
1976 . . .	101.1	100.5	103.1	98.9	97.8	98.4	95.9
1977 . . .	100.0	100.0	100.0	100.0	100.0	100.0	100.0
1978 . . .	100.8	100.1	103.1	95.6	94.8	95.5	92.7
1979 . . .	103.2	101.7	106.0	114.7	111.1	112.8	106.2
1980 . . .	96.3	99.6	88.1	97.4	101.1	97.8	110.6
	Average annual rates of change (percent)[1]						
1958–80	2.6	2.7	2.4	4.2	1.5	1.5	1.8
1958–65	1.7	1.0	3.0	3.9	2.2	2.9	([2])
1965–74	3.3	3.4	2.9	3.7	0.5	0.4	0.8
1974–80	0.2	1.2	−2.9	−0.1	−0.3	−1.4	2.9

[1] Based on the least squares trend of the logarithms of the index numbers.
[2] Rate of change is less than 0.05 percent.

The industry has a few very large firms with numerous establishments making a variety of equipment—tractors, combines, and other harvesting equipment, crop sprayers, plows, harrows, planters, cultivators, hay balers, and fertilizing equipment. These firms are highly integrated and manufacture many of the parts that are assembled into the final products, including both gasoline and diesel engines, as well as replacement parts for the older units in operation. The large firms generally produce the larger equipment, such as grain harvesting combines, 4-wheel drive tractors, and accessories. There are numerous medium and small firms in the industry. They usually specialize in a particular line or type of equipment, such as milking, poultry, or irrigation equipment. Many of them serve local markets for highly specialized equipment. The smaller firms also make lawn and garden equipment, such as walk-behind lawnmowers and snowblowers.

Farm machinery manufacturers are concentrated in the Farm Belt, with most plants in midwestern States—Illinois, Wisconsin, Minnesota, Iowa, Nebraska, and

Kansas. Texas and California also have a large number of plants.

The largest export market for U.S. manufacturers is Canada. In turn, Canada provides the largest amount of imports of farm machinery into the United States.

Employment and hours rapidly adjusted

Over the 1958–80 period, the number and hours of production workers and nonproduction workers in the farm machinery industry have grown at similar rates. Production workers increased at an average annual rate of 1.7 percent and their hours grew 1.5 percent. Nonproduction workers grew at rate of 1.7 percent, and their hours increased at a rate of 1.8 percent.

Year-to-year changes in employment and hours in this industry tend to move in a similar but less volatile pattern than changes in output. This indicates that the industry can adjust its hours and employment fairly rapidly to changing demand. For example, when demand is falling overtime usually is cut, the number of shifts worked are reduced, the normal summer shutdowns may be extended, and workers may be laid off.

The extent of the adjustments in hours due to changes in demand is influenced by the occupational makeup of the work force. In the farm machinery industry, the largest occupational group is operatives, most of whom are assemblers. Welders, precision machine operators, punch and stamp machine operators, and transportation operators also are important. These employees, along with laborers (mainly freight handlers) are most affected by reductions in demand. The industry also employs a large group of craftworkers—machinists, mechanics, tool and die makers, and blue-collar supervisors.[3] Craftworkers are least affected by declines in production; because of their skill levels, employers are reluctant to lay them off for fear that they may not be available when demand picks up.

Technology aids productivity

Technological change varies greatly among plants in the farm machinery industry. The more advanced highly sophisticated equipment is used, for the most part, by larger firms engaged in mass production of various products. Slower changes are undertaken by the smaller firms which make short runs of highly specialized products and generally have limited capital.[4]

The level of complexity of farm machinery manufacturing differs greatly depending on the product, which can range from a simple plow pulled by a tractor to a complex self-propelled grain harvesting combine. However, there are factors common to most farm equipment manufacturing: most of the components are made of iron and steel; they are shaped by such processes as casting, cutting, stamping, punching, boring, and machining; and they are joined to form the final product in an assembly operation which uses welding and fastening with air powered tools. Farm machinery is usually finished by painting, either in the parts stage or as a completed unit.

Because of the complex nature of many of the products, the varied manufacturing operations involved in producing units, and the fact that farm machinery manufacturing is a mature industry with many old plants, there are numerous areas that are subject to technological change. The larger companies usually make most of the parts they assemble into the final product. Therefore, the technological innovations they employ cover a range of manufacturing operations and have resulted in significant labor savings.

During the 1960's, capital expenditures per employee for new plant and equipment were consistently below the average for all manufacturing industries. However, because of sustained demand for farm equipment in the early 1970's which strained the industry's capacity,[5] firms began to increase their capital expenditures for new plant and equipment. By 1975, capital expenditures per employee had almost tripled, compared to the level in 1970. This resulted in the installation of advanced manufacturing equipment and large scale plant modernization and probably was one of the factors leading to a higher rate of productivity increase during the 1970's than during the earlier decade.

Computers are among the widespread innovations with significant impact upon the industry. They are used for many functions, including inventory control, data collection, tracking progress of semi-completed products, design, and for numerous accounting and other business purposes. In recent years, computers have been more directly used for manufacturing operations on the factory floor.

Numerically controlled machine tools are used extensively by major companies in the manufacture of the parts used in assembling farm machinery. A recent innovation is computerized numerically controlled machine tools, which are more versatile than standard equipment because they can be programmed for changes by the operator rather than from tapes. One unit installed in a large firm is a completely computer-controlled gear case transfer line, using numerically controlled machine tools, where parts automatically go through 87 machining operations.[6]

One plant is experimenting with a change in machine tool layout, from the traditional setup consisting of banks of individual machines designed for a single operation to cells of machine tools based on workflow. This new layout requires high volume, but has cut bottlenecks in production and has resulted in operating efficiencies.

Automatic welding has replaced manual welding in a number of installations. In addition, industrial robots are being introduced for welding functions, resulting in more versatile automatic welding operations.

Significant efforts have been made to increase efficiency in materials handling and warehousing functions. These functions are very important because of the numerous parts that must be moved, the many operations that must be carried out, and the large size of the factories involved in the manufacture of the more complex farm machines. A number of plants have installed computerized automatic warehousing and materials handling systems. In one plant, such a system is used for the materials receiving warehouse. The system is located in a special high rise building attached to the single story plant. Materials are shipped in using the plant's containers, logged on the computer, and moved automatically to a preassigned location. When needed, they are called for by the computer, which automatically sends a remote controlled sideloader for them, and are sent via conveyor to the location requesting them. This warehouse is run by a single computer operator. The installation of this system resulted in substantial labor savings, while doubling warehouse capacity, because the previously used equipment required numerous forklift operators.

Sideloaders are an important innovation in the industry, even though they require operators. They are narrower and higher than the conventional forklifts which they replace, allowing for increased storage space and versatility in the warehouse. Sideloaders are increasingly being used in semi-automatic computerized high rise warehousing systems installed in a number of plants.

An example of the most advanced technology for assembly line manufacture in the industry is a recently built tractor plant designed specifically for computer control.[7] This plant is unique in that almost all phases of its operations are computer controlled or directed. The plant has high rise computerized automatic warehouses. The parts to be assembled are programmed to move in the correct sequence to produce a finished tractor via conveyor through the various assembly lines. This is a major advance over the system where parts are made in advance and stored until needed, boxes of parts are moved to the assembly line via forklift trucks, and assemblers pick the correct parts out of the boxes to assemble the final product. The new plant uses industrial robots for welding and painting. The robotic painting machines are programmed to move their spray guns to paint the correct part of the tractor chassis as it moves by on the conveyor line. This differs from conventional automatic spray painting equipment, which uses fixed spray guns, in that it more closely approximates a human spray painter. Almost all welds for the frame of the tractor cabs made at this plant are done on an electronically controlled automatic framing buck which is run by a single operator. The assembly lines are set up so that fasteners and other small parts are fed directly to the assemblers at the correct height for their use. This plant's design significantly cuts parts inventory, reduces handling, increases manufacturing efficiency, and results in overall labor savings.

Besides robotic painting, which is just being introduced in the industry, there are a number of other innovations that increase painting efficiency. One system, electrostatic painting, has been used for a number of years. In this process, electrically charged parts move through an automatic paint spray booth, with the paint mist attracted to the charged part. Another innovation is electric dip paint lines, in which charged parts are dipped into a paint-filled tank from which paint is precipitated out on the part. These systems have resulted in savings in both paint and labor.

While the advanced innovations are most readily adapted by the larger multiline companies, smaller firms in the industry tend to introduce new technology more slowly. Many of the latter specialize in a particular product, such as pipeline milking units or self-propelled irrigation systems. Although these units are usually produced from common components (pipes, tanks, spray guns, and pumps), they are generally assembled to fit a particular farmer's need. Because of the semicustom nature of production used by these smaller firms, it is difficult to adapt much of the available new technology which is designed for volume production. In addition, many of the smaller firms are located in rural areas near the farms they serve and do not have the access to the capital markets as do the major companies.

Future trends uncertain

Changes in output and productivity in the farm machinery industry are expected to continue to reflect changes in farm income. In the near future, the outlook for farm income is uncertain. It has been falling since 1979; and currently, there are pressures on farm prices that are expected to slash farm profits. In addition, such factors as high interest rates and high fertilizer and pesticide costs are also expected to reduce farm income. The export market is uncertain, and farm prices are down. This situation could result in a continuation of the recent negative pressure on demand for farm machinery. In addition, technological changes in the near future may be affected by the financial difficulties of a number of the major companies in the industry, which are expected to limit capital expenditures for new plant and equipment.

Over the long term, modernization of plant and equipment is expected to continue in the farm machinery industry, with particular emphasis on labor savings and cost reduction. These changes will be fueled by possible competition with Japan in the market for larger farm equipment, which is presently dominated by U.S. concerns. Japan currently holds a large share of the U.S. market for small tractors.[8] The future will see growing installation of automatic welding equipment and increasing use of industrial robots for welding, painting, and other high volume, difficult operations. Computers will increasingly be used for manufacturing operations and in design functions. □

FOOTNOTES

[1] Average annual rates of change are based on the linear least squares trends of the logarithms of the index numbers. The farm machinery and equipment industry is designated industry 352 in the *Standard Industrial Classification Manual, 1972 Edition*, issued by the Office of Management and Budget. The industry comprises establishments primarily engaged in the manufacture of farm machinery and equipment, and garden tractors and lawn and garden equipment. A technical note describing the indexes is available from the Office of Productivity and Technology, Bureau of Labor Statistics, Washington, D.C. 20212. The indexes for this industry will be updated and included in the Bureau of Labor Statistics' annual bulletin, *Productivity Measures for Selected Industries*.

APPENDIX: Measurement techniques and limitations

Indexes of output per employee hour measure changes in the relation between the output of an industry and employee hours expended on that output. An index of output per employee hour is derived by dividing an index of output by an index of industry employee hours.

The preferred output index for manufacturing industries would be obtained from data on quantities of the various goods produced by the industry, each weighted (multiplied) by the employee hours required to produce one unit of each good in some specified base period. Thus, those goods which require more labor time to produce are given more importance in the index.

In the absence of adequate physical quantity data, the output index for this industry was constructed by a deflated value technique. The value of shipments of the various product classes were adjusted for price changes by appropriate Producer Price Indexes to derive real output measures. These, in turn, were combined with employee hour weights to derive the overall output measure. These procedures result in a final output index that is conceptually close to the preferred output measure.

Employment and employee hour indexes were derived from data from the Bureau of the Census. Employees and employee hours are each considered homogeneous and additive, and thus do not reflect changes in the qualitative aspects of labor such as skill and experience.

The indexes of output per employee hour do not measure any specific contributions, such as that of labor or capital. Rather, they reflect the joint effect of factors such as changes in technology, capital investment, capacity utilization, plant design and layout, skill and effort of the work force, managerial ability, and labor-management relations.

Hand and edge tools industry experiences slow rise in productivity

During 1958–80, annual productivity growth averaged just 1.3 percent, less than half the rate for manufacturing as a whole; industry employment grew by more than 50 percent

MARY K. FARRIS AND JAMES D. YORK

Despite the growing do-it-yourself market and the introduction of new technology, productivity growth has been sluggish in the manufacture of wrenches, hammers, axes, files, and other hand and edge tools. During the 23-year period ended in 1980, output per employee hour increased at less than half the annual rate of all manufacturing.

This modest productivity rise in the hand and edge tools industry stems from the very gradual nature of technological improvements. These improvements have been characterized by increases in equipment speed and the continued introduction of automated controls.

As measured by output per employee hour, productivity in the industry grew at an average annual rate of only 1.3 percent during 1958–80, compared with 2.8 percent for all manufacturing.[1] Output increased at a rate of 3.3 percent and employee hours, by 2.0 percent. (See table 1.)

During the period, the industry experienced moderate productivity growth in the early years and a significant slowdown in the later years—a pattern exhibited in general by the manufacturing sector. From 1958 to 1965, output per employee hour increased at an average annual rate of 2.6 percent. Productivity increased in every year except 1960. During 1965–80, productivity growth slowed significantly from the earlier period, advancing at an average rate of only 0.7 percent a year. The average annual output increase slowed to 2.6 percent while employee hours went up by 1.9 percent a year.

This marked falloff in productivity growth in turn reflects developments during two subperiods, 1965–73 and 1973–80, with different growth rates. From 1965 to 1973, productivity grew at an average annual rate of 1.3 percent, and during 1973–80, by 0.5 percent per year. The productivity trend was not steady, however, with both the largest increase and decrease occurring during the earlier subperiod. The largest drop, 6.4 percent, was in 1970, a recessionary year, during which output fell 7.1 percent and employee hours declined 0.7 percent. Both continued to decrease in 1971, but in 1972 the industry experienced a large turnaround; output rose by 17.1 percent, greatly outstripping the rise in employee hours of 9.2 percent. The resulting productivity gain of 7.2 percent was the largest during the study period.

The slow growth during the 1973–80 period reflected in part the 1974–75 recession. In 1974, output per employee hour dropped by 4.8 percent and in 1975, by 3.1 percent. Industry productivity rebounded strongly from the recession, however, rising by 3.9 percent in 1976 and by 2.5 percent in 1977. Productivity gains slowed in 1978 and 1979 as output growth moderated. The increase in 1978 was only 0.6 percent, followed by a rise of 3.7 percent in 1979. In 1980, with the economy experiencing a strong downturn, productivity fell by 5.1 percent.

Employment and plant size

The level of employment in the industry has grown 56 percent since 1958, from 30,300 to 47,200, equivalent

---

Mary K. Farris and James D. York are economists in the Division of Industry Productivity Studies, Bureau of Labor Statistics.

to an average annual increase of 2.2 percent. Employee hours advanced at an annual rate of 2.0 percent during the period, reflecting a slight decline in average hours per person. The number of production workers increased 53 percent; the share of the total work force accounted for by production workers has remained close to 80 percent.

A trend to larger plant size has resulted in an increase in the average number of employees per establishment. Between 1958 and 1977, the average number of employees per establishment rose from 40 to 65. The number of establishments with 500 employees or more almost tripled during this period, growing from 8 to 22. However, despite the trend to larger plant size, most establishments in the industry remain small. In 1977, 59 percent had fewer than 20 employees, although they only accounted for 5 percent of the shipments. The larger firms (100 employees or more) accounted for 79 percent of industry shipments.

Markets

Automotive distributors, industrial distributors, and consumers constitute the major markets for handtools. The largest group of handtools consists of mechanics' hand service tools, the bulk of which is marketed by automotive jobbers or distributors. Some of these vendors are "wagon peddlers" who sell the tools directly to garages and professional mechanics, providing quality tools and service-oriented marketing. Mechanics' hand tools are a fast growing segment of the industry. Demand is generated from the design changes made by automakers (including the conversion to metric) necessitating the purchase of new tools by the professional mechanic.[2]

Table 1. Productivity and related indexes for hand and edge tools, 1958–80

[1977 = 100]

Year	Output per employee hour	Output	Employee hours	Employees
1958	74.0	47.2	63.8	64.5
1959	79.0	55.0	69.6	67.9
1960	77.0	52.1	67.7	66.2
1961	79.6	55.7	69.8	68.1
1962	81.5	60.8	74.6	71.7
1963	84.0	56.9	67.7	67.0
1964	86.1	61.5	71.4	69.6
1965	91.2	70.2	77.0	75.1
1966	88.8	75.6	85.1	80.9
1967	93.9	73.3	78.1	76.4
1968	95.5	74.4	77.9	78.6
1969	97.2	80.4	82.7	81.1
1970	91.0	74.7	82.1	80.2
1971	94.4	72.7	77.0	75.7
1972	101.2	85.1	84.1	83.6
1973	101.8	92.2	90.6	88.8
1974	96.9	87.1	89.9	89.4
1975	93.9	75.8	80.7	80.9
1976	97.6	85.1	87.2	87.7
1977	100.0	100.0	100.0	100.0
1978	100.6	107.8	107.2	106.8
1979	104.3	112.1	107.5	108.7
1980	99.0	95.5	96.5	100.4
	Average annual rates of change (in percent)			
1958–80	1.3	3.3	2.0	2.2
1975–80	1.4	6.1	4.7	5.2

Distribution to industrial users creates another market for handtools. Demand in this segment generally follows overall economic trends—rising during industrial expansion and slackening during economic downturns. Construction activity also has an impact on sales of handtools, especially heavy forged tools such as sledges and picks.

The burgeoning do-it-yourself market has influenced some domestic producers to orient their product lines toward the household market. Rising interest rates and declining housing starts have generated more remodeling and self-improvement projects which require tools. Expenditures for maintenance and repairs tripled during 1965–79, and construction improvements quadrupled.[3] In the 1970's, some companies redesigned their line of specialized professional tools to provide the amateur with popularly priced, good-quality versions. The proportion of the population in the household-forming years has been increasing, thus providing the industry with a potentially good future market. The do-it-yourself market is somewhat countercyclical, providing some cushion to the companies during economic downturns. Do-it-yourself sales grew 27 percent during the 1974–75 recession.[4]

Competition from imports has been intensifying in recent years and is becoming an increasingly important factor in the domestic market. Imports of all handtools as a percent of new supply (domestic shipments and imports) have increased considerably since 1968, rising from about 6 percent to 11.5 percent in 1979.[5] The export market has declined in relative importance during the last few years. Exports as a percent of domestic product shipments reached a peak during 1974 and 1975, rising to ratios of 15 and 16.2 percent. The ratio has declined steadily since then, falling to 12.4 percent in 1979.

Technological advancement

The hand and edge tools industry produces a wide variety of products ranging from wrenches of all types and sizes to striking tools such as hammers, axes, and sledges. The industry also makes garden equipment such as hoes, rakes, and forks.

Although the basic processes involved in the production of hand and edge tools have changed little over the period, there have been improvements in the equipment and methods used. Many of these changes have been evolutionary in nature and have occurred on an in-house basis, with individual plants developing much of their own equipment to improve productivity. The result has been faster equipment speeds, increasing automation of certain processes, and more rapid materials flow. The introduction of robots by some manufacturers has been part of the effort to achieve more complete mechanization of the production processes. Robots are an integral part of an automated materials handling operation. They are used to help move workpieces to and from forging presses and to and from the forging press dies, and to assist with other operations such as the movement of workpieces to and from the oil quenching process.

One of the most basic processes involved in the production of products requiring a high degree of strength and hardness is forging. The objective of forging is to "hot work" the steel into specific shapes, concentrating the grain structure and fiber formation at the point of greatest shock and stress. This results in the achievement of the utmost strength and toughness inherent in the specific grade of steel that is used. This is especially important for striking tools.

To make hand and edge tools, a steel bar is sheared to the desired length and is then heated in an electric, oil, or gas-fired furnace. The bar is heated to a plastic condition and is then transferred to the forging hammer. Typically, drop forging hammers using closed impression dies perform the actual forging operation. (However, forging presses can also be used.) Intermittent blows of the hammer refine the steel billet or bar through a series of cavities in the die attaining the required shape in the finishing impression. A matched set of dies is used, with the lower die remaining stationary while the upper die vertically strikes the steel bar. Separate die impressions are used for preliminary and final forming operations.

Improvements in the ovens used to heat the metal for the forging operation have contributed to faster production rates. The speed with which these ovens can raise the temperature of the metal to the necessary level has improved, thus reducing the time needed for heating. Improved ovens have also reduced the amount of excess metal that needs to be removed from forged pieces, resulting in less finishing work.

There has been increasing mechanization in the "feeding" of metal to the forging equipment. Correspondingly, the operating speed of the forging equipment has also been improved. It is important that the proper temperature for the particular metal and the specific job be maintained throughout the successive stages of forging. The faster forging equipment has facilitated this and has thus reduced the problems associated with reheating.

In recent years, some plants have adopted horizontal impact forging equipment, which provides a high degree of automation. The piece of metal being worked is moved along by an electrically controlled manipulator. The dies, which are attached to pneumatically powered rams, act on the metal pieces horizontally as they shape them. The pieces are automatically moved from impression to impression within the die as successive stages of forging are carried out. The automatic control of the dies and the movement of the workpieces results in reduced labor requirements.

After forging is completed, a trimmer press may be used to remove the excess (flash) metal squeezed out by the impact pressure. Grinding and polishing operations may subsequently be performed on the forged piece of metal. Improvements in grinding and polishing equipment have also contributed to productivity gains; both procedures were formerly done with hand-fed and hand-held equipment. However, manufacturers have increasingly been adopting equipment which permits these operations to be performed on a continuous flow basis. Further reduction in the time required for grinding and polishing has been achieved through redesign of the product to reduce the surfaces which need to be worked on.

Heat treating of the forged pieces is frequently performed for various reasons such as achieving a more uniform grain structure, relieving stresses, hardening the surface, and increasing the ease of machining. Improvements in heat treating ovens, including better controls, have aided productivity. Increasing automation in heat treating has reduced the operators' work in this process.

The adoption of cold forming techniques is also aiding productivity. In the cold forming process, dies are still used to give the workpieces their final shape. However, advancements in the feeding mechanisms permit preforming of the pieces to such an extent that they can enter the dies without the usual need for heating. This technique is becoming increasingly popular, especially in the production of mechanics' hand tools.

Some manufacturers have achieved additional efficiencies through the use of edge hardening equipment. For items whose strength requirements are primarily limited to edge strength, such as hedge shears, this can mean faster production because the hardening of the workpiece is concentrated only on critical edges versus the whole piece.

Efficiencies have also occurred in the broaching operation, which is the metal cutting process that enlarges or changes the contour of the tool openings (for example, wrench openings). The increased use of manipulators, which control point-to-point movement of workpieces, has reduced the work performed by operators.

Computers have encouraged productivity growth in several ways. In addition to helping with administrative functions such as payroll and inventory, the computer has proven valuable for production planning. Its use enables many of the activities involved in daily production operations to be scheduled more efficiently. Computers also aid in coordinating the setup of production lines and the scheduling of die changes and downtime. This contributes to better utilization of die shops and other related in-house functions.

The outlook

Productivity should benefit from continued mechanization of production processes and gradual improvements in equipment. Continued introduction of robots and the increasing adoption of cold forming techniques should be contributing factors, as will the expanded use of computer technology.

Horizontal impact forging equipment may be a factor in future productivity increases as more plants adopt this technology, especially where long production runs are involved. The cost and setup time associated with this equipment, however, may hinder its adoption. The demand for industry output has benefited from growth in the do-it-yourself market and demographic factors suggest that this trend could continue. However, competition from imports, as measured by the import penetration ratio, has been increasing—as a percent of new supply they rose from 7.5 percent in 1975 to 11.5 percent in 1979. ☐

APPENDIX: Measurement techniques and limitations

Indexes of output per employee hour measure changes in the relation between the output of an industry and employee hours expended on that output. An index of output per employee hour is derived by dividing an index of output by an index of industry employee hours.

The preferred output index for manufacturing industries would be obtained from data on quantities of the various goods produced by the industry, each weighted (multiplied) by the employee hours required to produce one unit of each good in some specified base period. Thus, those goods which require more labor time to produce are given more importance in the index.

In the absence of adequate physical quantity data, the output index for this industry was constructed using a deflated value technique. The value of shipments of the various product classes were adjusted for price changes by appropriate Producer Price Indexes to derive real output measures. These, in turn, were combined with employee-hour weights to derive the overall output measure. The result is a final output index that is conceptually close to the preferred output measure.

Employment and employee-hour indexes were derived from data published by the Bureau of the Census because BLS data were not available. Employees and employee hours are each considered homogeneous and additive, and thus do not reflect changes in the qualitative aspects of labor, such as skill and experience.

The indexes of output per employee hour do not measure any specific contributions, such as that of labor or capital. Rather, they reflect the joint effect of factors such as changes in technology, capital investment, capacity utilization, plant design and layout, skill and effort of the work force, managerial ability, and labor-management relations.

FOOTNOTES

[1] The hand and edge tool industry is composed of establishments primarily engaged in the manufacture of files and other hand and edge tools for metalworking, woodworking, and general maintenance. The industry is designated as SIC 3423 in the *Standard Industrial Classification Manual, 1972*. Establishments primarily engaged in the manufacture of saws are classified in industry 3425 and power-driven hand tools in 3546. All average annual rates of change are based on the linear least squares trends of the logarithms of the index numbers. Extension of the indexes will appear in the annual BLS Bulletin, *Productivity Measures for Selected Industries*.

[5] The import penetration ratio is calculated by dividing the value of shipments of imports by the value of new supply, where new supply is defined as the sum of the value of imports and domestic product shipments.

A Review Essay

The productivity puzzle: numbers alone won't solve it

From vantage points in management, labor, academia, and government, contributors to four recent books grapple with the productivity slowdown, with little help from economic theory

PAUL S. ADLER

Over the last two decades, there has been a major decline in the rate of growth in U.S. productivity. The lag in the ratio of output to input has also occurred in many other industrial countries, including Japan.

Orthodox economic theory hypothesizes a basically technical link between trends in output and input, namely, the production function. This hypothesis has been put to a severe test, for the precise extent, the origins, and the significance of the productivity slowdown are yet to be analyzed with a clarity that would demonstrate the usefulness of traditional economics in analyzing such problems.

There is, in particular, a surprising contrast between the wealth of studies that attempt to quantify the decline and calculate its causes, and the poverty of material on the role played by such a lag in macroeconomic performance. It should be remembered that, in general, at a company and an industry level, labor productivity and profitability are *not* well correlated, and that in capitalist economies decisions are based on the latter, *not* the former. Paul Samuelson's neoclassical paradigm claims its originality in the capacity to link the two factors, in a synthesis of micro- and macro-economics. But so far, this approach has not shed light on the most elementary part of the productivity puzzle: Is the productivity slowdown basically a cause or an effect of current economic problems?

Research on productivity thus progresses somewhat unevenly. Three foci of study have emerged: data analysis, study of management practices, and research into labor relations and conditions. *Productivity: Prospects for Growth*, edited by Jerome Rosow, deals with all three subjects. The interdependence of the three themes makes this presentation most judicious. Three other recent books have also addressed one or other of these matters. Before discussing the major issues, we will identify the overlapping concerns of the four volumes.

Productivity: Prospects for Growth includes five contributions to the task of data analysis. Solomon Fabricant of New York University and Dale Jorgenson of Harvard University present the growth accounting data, Jerome Mark of the Bureau of Labor Statistics, the measurement consideration, and Howard Samuel and Rudy Oswald of the AFL-CIO, their views on the role of foreign trade and labor unions.

The reader seeking more detail on current data analysis methods can consult *Aggregate and Industry-Level*

Paul S. Adler, a research economist with the Employment Research Center of the French Ministry of Labor, has been a guest scholar at the Brookings Institution and the Bureau of Labor Statistics. He is currently a visiting assistant professor of economics at Barnard College, Columbia University, N.Y.

Productivity Analysis, edited by Ali Dogramaci and Nabil R. Adam, both of Rutgers University; this is the second volume of the Studies in Productivity Analysis series. Two papers address methodology: that by Ephraim Sudit of Rutgers University and Nachum Finger of Ben Gurion University presents a general survey and that by Douglas Moon of Columbia University, the dynamic input/output model. The formidable problems posed by time-series analysis are discussed by Lawrence Cohen of Columbia University and Salin Neftci of Boston College. Tom Boucher of Cornell University assesses technical change; J. R. Norsworthy and Michael Harper of the Bureau of Labor Statistics consider capital formation, and Frank Gollop of Boston College and Mark Roberts of Pennsylvania State University analyze imported intermediate inputs.

The next theme, management, is examined in *Productivity: Prospects for Growth* by John Donnelly, who discusses the role of the chief executive, and by Alfred Neal, former president of the Committee for Economic Development, who analyzes the role of the tax system. Exploring technological change at the corporate level are Reginald Jones, chairman of General Electric, John Diebold, chairman of the Diebold Group, Thomas Donahue, secretary-treasurer of the AFL–CIO, and Robert Ranftl of Hughes Aircraft Corp.

The problems of productivity management are also the theme of papers edited by Vernon M. Buehler and Y. Krishna Shetty, both of Utah State University, in *Productivity Improvement: Case Studies of Proven Practice.* Represented are 11 companies and three unions. Contributors also include Murray Weidenbaum, former chairman of the Council of Economic Advisers, and Clement Preiwisch of the General Accounting Office.

The last theme, dealing with labor, is discussed in *Productivity: Prospects for Growth* from four perspectives. Rosow of the Work in America Institute surveys the problems associated with the various "human factors" and discusses their possible remedies. Writing on worker participation are Stephen Fuller, vice president of General Motors, Douglas Fraser, president of the United Auto Workers, and Wayne Horvitz, director of the Federal Mediation and Conciliation Service.

These problems are given more theoretical treatment in Stephen Hill's *Competition and Control at Work: The New Industrial Sociology,* the fruit of his teaching at the London School of Economics.

The four books incorporate some of the most advanced thinking in this, somewhat fragmented, area of research. Our review will thus attempt to assess some of the strengths and weaknesses of the state of the art. The first two sections will deal with conceptual and analytical problems and will therefore consider the contributions of the Rosow volume and Dogramaci and Adam collection. The following two sections will cover the management and labor aspects, as they are discussed in Buehler and Shetty, Hill, and the other chapters of Rosow. In a concluding section, we sketch some alternative lines of research.

The conceptual problems of data analysis

The literature on the productivity problem shows little patience with the troublesome theoretical problems of economics. These books are no exception. Fabricant's overview gives theory scant attention; Mark's discussion of measurement problems includes an extensive survey of the reliability of our data, but from an exclusively pragmatic point of view. Sudit's discussion of methodological issues is broad-ranging but makes no effort to draw any conclusions concerning the value of the empirical work that is founded on fragile hypotheses. Most of his fellow contributors to the Dogramaci/Adam collection, concentrating on empirical industry-level and time-series analysis, struggle with the practical difficulties associated with these problems without the benefit of a viable theoretical framework. Not surprisingly, such studies are principally of interest to the professional student of productivity.

Two theoretical problems in particular would seem to merit discussion. Productivity analyses inspired by the neoclassical paradigm attempt to quantify the contribution of each factor of production to output growth. The productivity growth that cannot thus be explained, called the residual, has been attributed to technical change. Growth is thus decomposed into movements *along* a production function (representing a certain technology), and shifts *of* the production function (indicative of a change in technology). If this sounds plausible for small, marginal changes, Nelson[1] has already drawn attention to the absurdity of the attempt to extrapolate the procedure to major changes such as we have witnessed over the postwar period.

The second question warranting additional research takes us further back, into the great "Capital Debate" between Cambridge (U.S.) and Cambridge (U.K.). The conclusion was that the neoclassical attempt to base a theory of distribution on the theory of production was fatally flawed: even under competitive equilibrium conditions, the remuneration of capital is not determined by its marginal productivity, because the definition of a quantity of capital presupposes determination of the distributional variable. This conclusion vitiates much of the growth accounting exercise, because the calculation of a stock of plant and equipment—at first sight purely physical entities—involves a nontechnical factor like the rate of return. Multifactor productivity studies, however, continue to calculate a stock of capital (or a flow of capital services) by virtue, as C. E. Ferguson put it, of an "act of faith": "The question that confronts us is not whether the [British] Cambridge Criticism is theoretically valid. It is. Rather the question is an empirical or econometric one: is there sufficient substitutability within the system to establish neoclassical results? . . . Until the econometricians have the answer for us, placing reliance upon neoclassical economic theory is a matter of faith."[2] It is somewhat disconcerting to find the current productivity research pursued as if the Cambridge U.K. school had never existed.

Some relief from these attacks on the very legitimacy of growth accounting models may be forthcoming from the sophistication of more recent econometric techniques. Much of the capital debate concerned the circularity of reasoning in the neoclassical theory, attacking its explanatory power, but perhaps not its descriptive power. To our knowledge, however, none of the partisans of the growth accounting techniques has made this case. Most of the technical debates to date—for example, those surrounding the replacement of Laspeyres and Paasche indexes by Divisia indexes—are by comparison of limited import.

The basic problem posed by such theoretical interrogations concerns the usefulness of the neoclassical paradigm for dynamic analysis in conditions of real-world complexity. As Joan Robinson has written,[3] there is something inherently wrongheaded in trying "to find out from the record of what actually happened, what growth of output *would have been* if the value of capital had grown as much as it did without any technical progress having taken place." The value for long-term analysis of the distinction between shifts of and along a production function seems at best extremely limited.

The concrete problems of a choice of productivity indicators are thus posed against a backdrop of vast theoretical disputes; and the latter permeate the former. The usefulness of multifactor indexes, on the one hand, in attempting to define quantities of the different inputs, is limited by the need to assume that factors are remunerated at their marginal product. If this assumption is of dubious legitimacy for capital, the case of labor is not simple either. Obviously, different qualities of labor have different productive potentials; but it is much less clear that relative pay reflects these differences.

The use of simple labor productivity indexes, on the other hand, is theoretically uncontroversial. But their use does little to reduce the productivity puzzle to its purely quantitative dimension. The substitution of capital for labor must be somehow incorporated into the analysis. Relying on labor productivity, therefore, supposes the development of a model of accumulation, which the neoclassicists thought they had provided.

Beyond these properly economic disputes, there is also confusion over broader issues.

Measures of output, including those of the Bureau of Labor Statistics, are often approximate, especially in the many industries with no clearly defined products or quality range. In an extreme case, that of the computer equipment industry, the difficulty of the task of measuring quality change has led to total capitulation, and the price deflator is conventionally set at 1, as if there had been no qualitative improvement at all since the birth of the computer industry. Some, not implausible, estimates of quality changes in this industry can be shown to boost output measures so much that the productivity lag for manufacturing disappears entirely.[4]

The rapid development of the service sector aggravates this problem. It is remarkable that as we narrow our focus from GNP, to private business sector output, and further to manufacturing output, the productivity slowdown appears progressively less dramatic. This seems perhaps normal, when one contrasts automation trends in manufacturing with those of service industries like shoe-shining. But the image of a technically backward service sector is belied by the example of computerization in telecommunications, banking, and insurance.

Two hypotheses thus compete in explaining the difference between the roles of manufacturing and services in the productivity slowdown. The first is that we mismeasure and underestimate service output; pushed far enough, this hypothesis could lead to the argument that there has been no serious productivity lag. Against such skeptics, it can, however, be shown that in the manufacturing sector, too, and in particular in many industries where measurement problems are least important, there seems to have been a significant productivity slowdown. The second hypothesis reverses the perspective, to emphasize the collapse of the service sector's apparent productivity. Could this reflect a real breakdown

in the efficiency with which this sector performs its mediating and informational functions? Unfortunately, little research has been conducted on the industrial dynamics of these functions.[5]

Deeper conceptual problems are not absent here either: how should we treat nonmarket goods? Pollution control expenses are commonly included in the cost side of production, but are difficult to include in the output side as, for example, clean air. Do market prices bear sufficient relation to utility to justify our reliance on them for evaluating economic performance? There is a venerable tradition of rejecting output (and therefore productivity) statistics as irrelevant to real welfare. The rub, of course, is that even if the data reflect the specifically market forms of welfare calculation, it is such calculations which orient real-world decisions. As limited as these measures are, they therefore have a key role to play in analysis.

The Rosow and Dogramaci/Adam volumes give these problems but scant attention.

Looking for scapegoats

Beyond the conceptual and measurement difficulties, there has nevertheless probably been a fall in labor productivity growth rates. This deceleration is sufficiently important in a large enough range of indicators, both aggregate and industry level, to overcome most skepticism. Do we have an explanation for it?

In the aggregate data, the slowdown is particularly dramatic since 1973. In the total factor productivity framework, this shows up as a precipitous decline in the main factor contributing to growth, the residual. This fact alone should be sufficient to show that Edward F. Denison's interpretation of the residual as primarily reflecting advances in knowledge cannot be sustained.[6] Whatever slowdown one may imagine taking place in research and development, the accumulation of knowledge can hardly be imagined to have braked so suddenly.

A first hypothesis might be that companies today treat labor as a quasi-fixed factor, and that therefore the adjustment of employment to production is slower than it used to be. This has been verified statistically, and many of the contributors to the Buehler/Shetty volume claim that increased labor flexibility is the key to increasing corporate profitability. While this may explain a certain (downside) volatility of productivity ratios over the shorter period, the question remains as to why the slowdown persists.

Indeed, the U.S. debate has been characterized by a great resistance to the idea that the recent recessionary trends could be other than purely cyclical or exogenously generated. Jorgenson,[7] in *Productivity: Prospects for Growth* and elsewhere, develops the exogeneity thesis, arguing for the importance of energy prices in explaining the slowdown. The data are far from showing this; but, above all, one would want to ask: why have the major economies proved themselves to be so incapable of surmounting such a handicap? The vigor of the upturns in GNP growth since 1973 has slowed recognition in this country that the long-term growth path has been shifted downward.

Under the title "Free the Fortune 500," Weidenbaum presents the now-classic case for assigning the role of chief culprit to government regulation. No statistics, and certainly not Denison's, have been advanced to substantiate his claim. The text is a candidly ideological manifesto that gives the reader a glimpse into the mind set of the recently resigned head of the Council of Economic Advisers.

The most serious candidate for blame is capital formation—the object of a study by Norsworthy and Harper in *Aggregate and Industry-Level Productivity Analysis.* The proportion of GNP going to investment has been remarkably stable over the last decade, but as GNP growth has slowed, so has capital formation. Other data in this contribution indicate that the price of capital services sharply accelerated from 1973, almost reaching the rate of increase in hourly labor compensation. The combination of higher interest rates, massive increases in the labor force owing to the arrival of the baby-boom generation and to the "mobilization" of women, as well as more direct pressure on real wage levels, may have thus led to such a cheapening of labor relative to capital as to slow the substitution of the latter for the former.[8] The principal difficulty with these explanations of the productivity slowdown is that the reduction in investment *flows* only marginally affects the "productivity" of the *stock* of capital. A further hypothesis is explored by Alfred Neal in *Productivity: Prospects for Growth*; he blames "excessive" taxation for insufficient investment. The argument is weakened by the ubiquity of the slowdown in countries with widely different taxation trends. Energy costs have also been incriminated, their rise rendering redundant a certain fraction of the capital stock because of energy/equipment complementarities.

Any or all of these factors may have played a role, but a key lesson from John Maynard Keynes seems to have been forgotten: the "animal spirits" of the investor will surmount many such obstacles if the weather forecasts for the business climate are good.[9] In particular, that somewhat tired old culprit, deficiency in savings, cannot constitute a real brake in a modern economy in which investment is financed on a credit-based, forward-contract system. If business prospects are good, low levels of retained corporate earnings will be supplemented by extra external finance, and a lack of deposits in the lending institutions will be overcome by money-creating credit.

The problem would thus appear to be systemic rather than localized. Any particular difficulty can be surmounted, and, often, transformed into a stimulus. The search for the origin of, and the cure for, the productivity "problem" has therefore recently turned to management and labor, the major actors in a socioeconomic system, the dynamism of which may be faltering.

The role of management

The link between productivity and management is difficult to establish because product change and marketing flexibility are often more direct determinants of commercial survival and success than the technical efficiency with which a firm produces a hypothetically stable product. Accordingly, management itself tracks profitability rather than the more abstract notion of productivity.

The second part of Productivity: Prospects for Growth discusses a number of management problems related to the productivity issue. The principal area of analysis is the dynamism of technological change in the firm. Diebold sketches the (well known and still) fascinating account of the Office of Tomorrow, with a refreshingly pragmatic touch as to the limits both of the current technology and above all of its impact on office-work productivity. This contribution is valuable in reminding us that the availability of new technologies does not guarantee their rapid implementation—the delays are often measured in decades. Furthermore, implementation does not guarantee improvement of the standard productivity indexes, for new technologies create new tasks.

Other contributions include a disappointingly low-key union assessment of technological trends by Donahue, somewhat in contrast with the more thought-provoking piece by Oswald, AFL-CIO research director, on the general productivity question. The contribution of John Donnelly, the chairman of Donnelly Mirrors, Inc., is useful in outlining one manager's perception of the importance of practical labor-management cooperation in the framework of a Scanlon Plan.

This latter approach to labor, seeking to transform the presence of unions from a handicap into an advantage for corporate competitiveness, is in sad contrast to the approaches outlined in the case study volume published by AMACOM (a division of American Management Associations). The reader cannot but be impressed by the presence of such important companies as Kaiser Aluminum and Chemicals, Hughes Aircraft, and Burger King, even if the papers themselves are disappointingly short and lacking in detail. The message is basically that productivity demands more Taylorism, more control, more incentive pay schemes, and a small dose of Japanese-style Quality Circles. The last are designed to capitalize on workers' intimate knowledge of the production process. The Quality Circle view, in contrast to the "quality of worklife" philosophy to which Rosow and others allude, excludes any commitment to real cooperation in which the gains of labor would not be premised on the *prior* increase of company profits.

Some cracks do, nevertheless, appear in the management orthodoxy. Nucor Corp. insists on the importance of job security and has implemented group bonus schemes that include foremen and maintenance crew. Crompton Co., Inc., has instituted a 36-hour, 3-day workweek paid 40 hours. Hughes Aircraft declares its commitment to designing "meaningful" jobs by enlarging the range of tasks.

The union contributions by Cass Alvin of the AFL-CIO echo somewhat alone in this landscape. The conservatism of his interlocutors would indeed seem to constitute a major handicap in putting the United States back onto the map of innovative entrepreneurship. Abernathy, Clarke, Hayes, and Kantrow[10] have recently launched a major critique of this conservatism. They attribute the decline in the relative strength of U.S. companies to the short-term, bottom-line myopia of corporate decisionmaking. Overemphasis on quarterly and annual results, according to the Harvard authors, cripples American corporations' capacity for long-term technological programming. Symptomatic of the disease is the U.S. managers' tendency, perfectly explicit in the case studies, and above all in the "Free the Fortune 500" contribution, to interpret every constraint on their prerogatives as an intolerable shackle on individual creativity. Whence the paradox: in the United States, where Government intervention and unions are smaller and weaker than in most other developed countries, the blame attributed to Government and unions in causing the current crisis is greatest.

The difficulty, of course, with this critique of management, is that in less expert hands it can easily slide into the same "blame the victim" mode that constitutes one of management's own shortcomings. Can one sustain the argument that the current economic woes of the United States are principally due to a particularly incompetent group of managers? Is not their myopia the most rational programming strategy in a period of great uncertainty? Is it not the flip side of the flexibility of operations that European managers so envy? Is not long-term technological programming vastly easier for those in second place who are imitating the frontrunner?[11]

Alternatively, one could perhaps hypothesize that the cyclical characteristics of capitalist growth can be dampened in the shorter term but not eliminated. The problem is thus rephrased: in the current worldwide recessionary climate the only way to limit the cost of the market system's congenital myopia is by aligning short- and long-term prospects. Such a reconnection implies a stabilization of macroeconomic conditions. Because markets are in themselves unable to provide such stability, capitalist growth seems to necessitate its imposition by non-market forces, via the further institutionalization of social consensus and conflict-resolution mechanisms.

The role of labor

The frequency with which incentive pay schemes are mentioned by the contributors to the case studies is perhaps not to be simply attributed to the blame-the-victim syndrome. Assuring the cooperation of labor is a major permanent task; poor labor relations can be very costly in terms of excess supervisory personnel, of under-performance of workers, of underutilization of plant, and of lack of product quality and timeliness. If these costs are less important than those associated with a deficit of technical and organizational adaptation, they are by no means negligible.

Stephen Hill's book presents a valuable framework for the analysis of these problems. Written from an English perspective, but with a solid grasp of U.S. developments, its dual reference to Max Weber and to a context where class conflict is manifest could prove a tonic for a U.S. audience. Especially in the current period when labor leaders have rediscovered the pertinence of a "class war" rhetoric.

U.S. industrial sociology has been dominated by a Durkheimian perspective which privileges the reproduction of a community of values. The absence of consensus thus constitutes the horizon of much social thinking: conflict is ever present but always on the horizon, beyond theoretical grasp. This approach contrasts with that of Weber, for whom the conflict of interests is the starting point of social analysis.

The fundamental hypothesis of Hill's work is that antagonistic interests compete within the firm. This conflict is not just over income distribution, but also over power, and in particular allocative power on the shop floor (work rules, staffing patterns and levels, work intensity, and so on). The fact that U.S. unions are seen as having de-emphasized allocative struggles in exchange for concessions in income distribution should not, in Hill's view, be interpreted as implying that shop-floor conflicts can be relegated to the status of a problem of maintaining consensus within the unions. The basic separation of ownership or control and productive activity—as opposed to their unity in a cooperative system—makes competition and conflict primary, if not permanent, features of the capitalist firm.

Hill's Weberianism is not the diluted version to which U.S. audiences are accustomed. Power within the capitalist firm is inexorably asymmetrical. The wage relation is a power relation, not just a "contract," because the worker, while free not to enter this or that *particular* employment contract, must enter *some* contract on pain of distressing unemployment. (Milton Friedman's identification of Capitalism and Freedom rests on obscuring the general constraint in order to vaunt the freedom of its particularity.)

This leads to an interesting if somewhat fragmented discussion of Taylorism that contrasts favorably with what one often finds in the U.S. literature. Hill follows much of the recent research which characterizes Taylorism as an expression of this asymmetry in the labor process: management control over the immediate labor process is gained at the expense of craft-type worker autonomy. But he tempers this account by a discussion of the limits of Taylorism: its partial adoption in management circles, the resistance of workers to its effects, and, most importantly, the fact that the production process always necessitates some degree of cooperation—even within the framework of conflict.

The conflictuality of labor-management relations is, in this perspective, somewhat independent of the degree of institutionalization taken by the forms of its resolution. By contrast, U.S. discussion of quality of worklife programs seems hampered by the assumption that *cooperative* and *adversarial* relations can and should be two totally distinct modes of labor-management interaction. It is as if an overly consensual (and individualist) ideology blocked recognition by management and by unions that plant-level conflict was healthy and that cooperative moments *within* this conflictual relation were perfectly normal. Whence a fruitless polarization between the cynics and the naive.

The import of such research for the productivity puzzle is considerable, for many discussants locate the root of productivity decline in shop-floor tensions. The value of Hill's work is to remind such "radicals"—who appear at all points of the political spectrum—that growth in capitalist economies is not a zero-sum game. Workers' gains are not simply capitalists' losses, because in the longer run such gains are one of the most potent stimuli to technical change and hence to productivity growth. Whether worker resistance plays this role depends on the dynamism of the system.

The dynamism of socioeconomic systems

The productivity puzzle is a valuable indicator of the current state of economics, reflecting this discipline's difficulties—heoretical, quantitative, historical, and sociological. Richard Nelson has drawn the uncomplimentary parallel with the drunk looking for his lost watch under the lamp post "because that's where the light is." But why is the economics profession tipsy? Part of the reason may be its excessive focus on formulating policy recommendations, an objective not always conducive to major theoretical research.

The role played by this policy focus might, however, shift from debilitating to revivifying. The urgent need for vigorous policy remedies to current economic problems will not, we believe, be satisfied by a reliance on the automaticity of market adjustments. The demand for serious policy may thus, indirectly, become a stimulus for the revival of those theoretical trends that have for too long been relegated to the margins of economic theory: the heterodoxies of institutionalist and "fundamentalist" Keynesian theories.

The most fruitful areas of research may be at the intersection of Joseph Schumpeter and Nelson, in its proximity with that developed by certain French researchers[12] along the lines suggested by Michel Aglietta.[13] It would associate the analysis of macroeconomics to that of social institutions, going beyond the neoclassical, market-centered model by breaking with its implicit assumption that real developments, such as a productivity slowdown, can be accounted for by the juxtaposition of purely exogenous shocks and the spontaneous equilibrating market mechanism.

Market mechanisms need to be integrated into a historical model that explains their (always limited) pertinence to any given epoch. Periods of economic history are thus distinguished according to their money-creation regimes, wage-setting institutions, price determination mechanisms, and international trade hierarchies. The coherence of these social forms with the dominant macroeconomic relations of productivity and income growth—"deepening" or "widening" modes of accumulation—assures a harmonious balance in the expansion of output and demand; their incoherence generates a protracted, Kondratieff-like period of instability.

Periods of coherence naturally exhaust their dynamism. Tensions accumulate. The diffusion of finite sets of organizational and technological innovations reaches higher plateaus. Virtuous circles become vicious. No meta-auctioneer guarantees the timely replacement of failing system-stabilizers.

In such a perspective, the downward shift in growth paths, of which the productivity deceleration is but a symptom, is attributable neither to a single cause nor the accidental conjunction of several causes. Longer downswings are part of our economic history, as the system exhausts and then recreates the social-structural conditions of accumulation.

Economic history, the real history of cycles, short and long, of accumulation and crashes, is made in the interstices of "economics" as Academia currently imagines it. At least, such might be the lesson of the productivity puzzle. ☐

How Sweden combats unemployment among young and older workers

Joblessness among the 16- to 24-year-olds and those 45 years and over in Sweden, although low by American standards, worsened during the recessions of the 1970's; government responded with innovative policies to increase job prospects for these groups

HELEN GINSBURG

The Swedish Government Bill of 1966, which forms the basis of labor market guidelines, states that its aim is to "achieve and maintain full, productive and freely chosen employment." Although unemployment only averaged about 2 percent in the 1970's, that goal has not yet been attained for all young people, women, immigrants, older workers, and the disabled. The proportion who are unemployed in these groups is small by American standards, but not by Swedish standards. One of the major challenges of Swedish society, with its strong commitment to full employment, is to provide jobs for these workers. This article discusses some of the policies Sweden uses to contend with unemployment among its young (16 to 24 years) and older (45 years and over) workers.

Causes of youth unemployment

As recently as the mid-1960's, jobs were plentiful for most Swedish youngsters, regardless of whether they had only completed the 9-year comprehensive school (which is compulsory for 7- to 16-year-olds), upper secondary school (which follows), or had graduated from a university.[1]

In the 1970's, job prospects became less promising. Sweden's first recession of the 1970's, starting in 1971, drove the annual unemployment rate up to 2.5 percent and slightly higher for several consecutive years. Youth were hard hit. Since then, unemployment rates of 7 and 8 percent have been common for 16- to 19-year-olds (reaching 9 percent in 1981), as have rates of 3 to 5 percent for 20- to 24-year-olds. (See table 1.) Myriad factors affected the rise of youth employment. For example, apprenticeships practically disappeared and most companies that once provided on-the-job training for youngsters no longer did so because many already received training in the secondary schools. In the 1970's, manufacturing employment stagnated as a result of productivity gains that reduced labor requirements, recessions, structural problems that beset important export industries, and the tendency of Swedish transnational corporations to locate more manufacturing jobs abroad. Thus, many blue-collar jobs that might have been available to youngsters disappeared. Gone, too, were other jobs—such as delivering packages—that once gave some employment in small businesses. Most job creation was in the public sector, but some fast growing areas—for example, hospitals—were often out of bounds for persons under 18 years because they cannot

This article is excerpted by permission of the publisher from her forthcoming book, *Full Employment and Public Policy: The United States and Sweden* (Lexington, Mass., Lexington Books, D.C. Heath and Co., copyright 1982, D.C. Heath and Co.).

work at night, drive vehicles, or do other unsuitable work. And in some cases, housewives, who entered the labor force in large numbers, were hired in preference to the young.

In slack labor markets, lack of experience became a more important barrier to employment for young workers, and employers often claimed that wages for youths were too high.[2] Unlike the United States, Sweden has no minimum wage law, but the negotiated contracts that set most wages allow youths to earn less than adults. Partly as a result of the wage solidarity principle of the Swedish Trade Union Confederation (LO), to which most blue-collar workers belong, the youth to adult wage differential narrowed in the 1970's. (The aim of this policy is to reduce wage differentials in accordance with the rule of equal pay for equal work, regardless of the profitability of the firm.) However, the narrowing of the youth to adult differential has been occurring for three decades and some of it reflects the higher average age of young workers resulting from longer schooling. To the extent that this is a factor, subsidies that reduce the cost to the employer of hiring the young have been used in preference to lowering the differential. Swedish unions present no barriers to employment of the young —anyone who is hired is accepted as a member.

Some employers contend that employment security laws caused the youth unemployment problem. However, youth unemployment worsened before the advent of these laws, although employers may now be more reluctant to hire any workers but those perceived as "prime." Interestingly, the law permits hiring for a probationary period if sanctioned by a collective bargaining contract, which usually is the case. Also, many firms had "no hiring" policies in effect at times during the 1970's, especially in the middle of the decade.[3] These policies hurt new labor market entrants. And, with many policies aimed at maintaining employment, recovery from a recession often meant that some additional demand for labor could be met without additional hiring.

In the early 1970's, about 70 percent of Swedish comprehensive school graduates went directly to upper secondary school, and that figure was about 85 percent by the end of the decade.[4] Secondary schools in Sweden are more specialized and more vocationally-oriented than those in the United States. There are more than 20 lines or courses of study that last from 2 to 4 years. Lines are practical or theoretical (academic) and designed to prepare a student for further education, although some higher education is now also open to those who study practical lines.[5] Youngsters from lower socioeconomic backgrounds are more likely to either take shorter, more practical courses and to drop out along the way, or not to enter secondary school at all. Hence, youth unemployment has a class as well as an age dimension. Changes in higher education during the 1970's worsened the relative position of the youngest and least educated workers by increasing the supply of better educated young workers. Unemployment among university graduates led to a substantial decline in enrollment in higher education, which added to the competition in the job market. Some college graduates had to take lower level jobs that they would not have accepted in previous years, including jobs that once had gone to secondary school graduates. These better educated young people were often preferred by employers and this caused a chain reaction that reverberated down the line and ultimately affected even the comprehensive school graduate.[6] Similar competition results from another factor. University applicants with work experience are now given extra credit, making it easier for them to gain entrance. Hence, more students work for a few years before going on to higher education.

Policies to increase job prospects

Policies to combat youth unemployment are wide ranging and include those targeted at youth as well as those targeted at specific kinds of unemployment which disportionately affect young people. General economic policies, needless to say, are particularly important because recessions inevitably hit the young harder than adults.

Role of schools. Within the school system, there are efforts to inform students about the world of work. For example, students visit a variety of work sites in their last years of comprehensive school. In addition, there are vocational guidance officers in all schools, and the

1981	2.5	9.4	8.2	10.5	4.7	4.8	4.6

[1] Because of a conflict in the labor market, data exclude second quarter.

NOTE: Data are based on Sweden's Central Bureau of Statistics Labor Force Surveys. The unemployment rate is the percentage of the labor force that is unemployed.

Labor Market Board (a tripartite board which carries out labor market policies) provides personnel from its Public Employment Service to talk to secondary school students and at parents' meetings. Also, as part of its broad educational effort, the board prepares printed material and radio and television programs aimed at students.

There is excellent cooperation between the local Labor Market Boards and the Boards of Education. They work together to develop special courses in the adult municipal school system, and in folk high schools (a type of boarding school with no official syllabus or compulsory subject matter and run by local governments, churches, trade unions, temperance societies, and other nonprofit organizations). Labor Market Boards and Boards of Education also cooperate to develop courses in the regular school system and in the more than 50 government-sponsored labor market training centers located throughout Sweden.

Planning councils. Since 1977, there have been planning councils for youth in all municipalities. These are headed by local school authorities and include representatives of other municipal agencies, the Employment Service, labor, and management. Under this arrangement, schools are responsible for maintaining contact for 2 years with all students who leave compulsory school without continuing their education. Until these youths are 18 years of age, they must be guided and advised about jobs or other educational opportunities that may arise, such as special courses or the availability of additional openings in particular lines in the regular school system. The aim is to prevent out-of-work 16- and 17-year-olds from drifting aimlessly on their own.[7]

Occupational stereotyping. Breaking down the stereotyping of jobs by sex is considered very important in the fight against youth unemployment. Young women already in the labor market are encouraged to consider nontraditional jobs and greater efforts are being made within the school system, among employers, within the family, and in the media to stop the stereotyping of occupations.[8]

Monetary support. Cash assistance for those who have never worked or are otherwise ineligible for regular unemployment benefits was introduced in the 1970's with the young and women in mind. Persons who have finished secondary school (or the equivalent) are eligible for these benefits, which pay less than regular unemployment insurance, if they have unsuccessfully sought work for 3 months through the Employment Service. Those who have not completed secondary school and who are at least 16 years old must have worked for at least 5 months. Slightly more than half of all recipients of cash assistance at the end of the 1970's were under 25 years, representing only 30 percent of the unemployed in that age group.[9] However, some may have been receiving regular unemployment benefits. Sweden does not consider unemployment insurance a solution to joblessness among the young; it views such benefits as temporary income until something more substantive can be arranged—a job or training for a job.

Placement efforts. The Employment Service (at which almost all jobs must be listed) helps in the job search and often intensified placement efforts are made for youths. However, if employers demand an experienced worker or a highly skilled worker, there is little the service can do. Telephone follow-ups and even personal visits to job sites by placement officers have occasionally proven helpful in placing young people in jobs.

Relief work. Until the 1970's, there were few young people in labor market training or "relief work" (comparable to Public Service Employment jobs in the United States). With few exceptions, training was reserved for persons 20 years and over. The major thrust of relief work was to help adults in the work force adapt to changing demands for labor. With rising youth unemployment, the proportion of trainees under 25 years rose from 30 percent in 1969 to 38 percent in 1979.[10] In the 1970's, the age limit for relief work was relaxed and about 10 percent of the training slots were taken by teenagers.[11] Youngsters uncertain about their occupational choice were encouraged to try several types of jobs before deciding on further training or more formal education. Programs were developed for those with special problems who were turned off by ordinary schooling: groups of about eight young people were given alternating periods of general education and work—2 weeks of education followed by 6 to 8 weeks of relief work, repeated with different jobs.

The biggest expansion was in relief jobs at regular wages for the young. Between 1970 and 1979, the proportion of persons under age 25 in relief work rose from 4 percent to 68 percent. The expansion was particularly important for young women—83 percent of women, but only 57 percent of men in relief work in 1979 were that young.[12] In the public sector, office work, maintenance and repair work, environmental conservation, and care of children and the elderly were popular, to cite some examples. Private sector employees who hired young people referred by the Employment Service were also able to provide relief work, and received a 75-percent subsidy if these jobs were in addition to their regular recruitment and included some useful training. The hope that employers would offer regular jobs after the 6-month maximum for relief work often did not materialize. Sometimes a succession of relief workers were taken on for 6 months, and training was sometimes lacking or cursory.

In the case of 16- and 17-year-olds, the government feared that labor market training and relief work would compete with regular schooling and might even induce students to quit school for short-term jobs. Secondary school students in Sweden receive a stipend which, in 1979, was 208 kronor a month (a krona was equivalent to 22 cents in U.S. currencies in 1979), while relief jobs paid from 3,000 to 4,000 kronor a month.

Did this high pay for students lure them away from school and into the temporary jobs? That, along with questions about the reliability of some of the training were major reasons for the policy changes toward 16- and 17-year-olds approved by Parliament in June 1980. The new approach is less costly and possibly that was also a consideration of the government. Both relief work and labor market training were considered inappropriate for youths under 18 years. Now, 16- and 17-year-olds are not eligible for these programs. Instead, they are encouraged to return to secondary school. If they do not wish to do that, they are offered additional vocational education and training within industry or some flexible "sandwich course" arrangement of education and practical work experience, with the responsibility shifted from the Labor Market Board to the educational authorities. The stipend paid is the same as for other secondary school students. The Social Democrats (not in power at the time) opposed ending relief work, contending that to do so would retreat from the Parliament's goal of a "youth guarantee" to insure either training or employment for all out-of-school youth.[13] The success of the new program will surely depend on the adequacy of the training and the ability to attract back into the program students who had become alienated from the educational establishment. Not enough time has elapsed to know the results, but early reports are positive. However, the ability to absorb the young into the labor market in the 1980's will also depend on the state of the economy.

Special protection for older workers

For both men and women in Sweden, unemployment declines steadily with age until it reaches a trough of about 1 percent among 45- to 54-year-olds and then rises to about 2 percent among 55- to 65-year-olds. (See table 2.) Beyond age 65, there appears to be no unemployment, but labor force participation is very low, 14 percent for men and 4 percent for women (1979). Many older workers who lose their jobs slip into retirement, as the pensionable age was lowered to 65 during the 1970's. Although older workers are less likely to lose their jobs, they are out of work longer than those who are younger. This pattern is the same as that in the United States.

Table 2. Unemployment rates in Sweden, by age and sex, 1979–81

Age	Total			Men			Women		
	1979	1980	1981	1979	1980	1981	1979	1980	1981
16–74 years . .	2.1	2.0	2.5	1.9	1.7	2.4	2.3	2.3	2.6
16 to 19 . . .	7.4	7.8	9.4	7.0	6.5	8.2	7.9	8.8	10.5
20 to 24 . . .	3.7	3.7	4.7	3.6	3.5	4.8	3.8	3.9	4.6
25 to 34 . . .	1.9	1.8	2.3	1.6	1.5	2.2	2.1	2.2	2.5
35 to 44 . . .	1.2	1.1	1.4	.9	.8	1.3	1.5	1.4	2.5
45 to 54 . . .	1.0	1.0	1.3	.9	.9	1.4	1.1	1.1	1.2
55 to 64 . . .	2.0	1.8	2.0	1.8	1.6	2.2	2.2	1.8	1.8
65 to 74 . . .	.0	.0	.0	.0	.0	.0	.0	.0	.0

NOTE: These data are based on Sweden's Central Bureau of Statistics, Labor Force Sample Surveys. The unemployment rate is the percentage of the labor force that is unemployed.

The situation of older workers started to deteriorate in the late 1960's and early 1970's, partly because of the demand for higher productivity, the LO contends.[14] During that time, whenever there was a plant closing or cutback in production, most of those who lost their jobs found others. But, even in nonrecession years, a residual group was left without work, usually older workers and the handicapped. The recession of the early 1970's made their plight worse. Many of the laws that protect these workers came after that period, partly in response to these developments in the labor market. Policies towards older workers fall into two main categories: those that seek to maintain employment and those that seek to maintain income when there is no work. (Policies for disabled workers such as subsidized employment and workplace and job redesign also apply to many older workers. These are not discussed in this article.)

Keeping older workers at work

Much of the sweeping labor legislation of the 1970's aimed at increasing the security of all workers. But the vulnerable status of older workers and the handicapped was recognized and they were given special protection. The Security of Employment Act requires prior notice of dismissal and also requires the time of notice to vary with age, reaching a maximum of 6 months for employees older than 45 years.[15] Seniority determines the order of dismissal and that tends to protect older workers. The computation of the length of service for those over 45 years is also governed by more generous rules. And, the Security of Employment Act states that there must be reasonable grounds for dismissal. Illness and reduced work capacity are not generally considered sufficient grounds, unless an employee is "no longer capable of doing work of any significance." In the case of illness, the workers are given disability pensions; if they are unable to carry a full work load, the employer must find less demanding work for them. Thus, there is great job security for older (and disabled) workers whose capacity to do certain work has diminished or who cannot perform their old jobs but can do other types of work.

The Promotion of Employment Act helps both older and handicapped workers by requiring that the County Labor Market Board be notified before any layoff or plant closing. The employer must, if requested, provide information about the number of employees above a certain age or with diminished work capacity, so that special plans can be made for their reemployment, although these employees are usually retained unless the plant actually shuts down. That act also gives the County Board the day-to-day responsibility of consulting with employers—even when no dismissals are involved—in order to improve the situation of elderly or handicapped workers already within firms and to promote their recruitment.[16] Thus, the primary thrust of policies toward older workers is to prevent their unemployment by maintaining their existing jobs.

Labor market training is not extensively used by the older worker. During the 1979–80 fiscal year, for example, about 15 percent of the unemployed were over 55 years old, but only 2 percent of those in labor market training (excluding inplant training) were in that age group.[17] In most cases, the problem confronting older workers is not lack of skill, but lack of an employer who will hire them. Relocation is not used much either, because older workers have so many ties to a locality and relatively few working years left.

Some older workers are in relief work. Those 45 years and older held about 45 percent of all relief jobs in 1975. But, the large expansion of relief work in the late 1970's was aimed at persons under age 25; as a result, only 13 percent of relief workers were age 45 or older at the beginning of 1979.[18]

Income support

Despite the protection given to older employed workers, unemployment does happen, particularly when plants close. And then, income support plays an important role. Regular unemployment benefits are usually payable for up to 60 weeks, but for persons age 56 to 64, benefits are payable for 90 weeks, if necessary. The Cash Labor Market Assistance, available to those who have exhausted benefits, also varies with age, rising from 30 weeks for persons under age 55, to 60 weeks for those age 55 to 59; for those age 60 and over, and for some structurally unemployed persons, benefits can be paid until age 65, when the normal retirement pension begins.

However, unemployed workers over age 60 often can qualify for a disability pension. The medical test is more lenient for older workers than for younger persons. If a person is considered permanently unemployed, there is no medical test at all, if he or she has exhausted regular benefits or has received cash labor market support for 90 weeks. Liberalization in granting disability pensions resulted from concern of the blue-collar workers' union for older workers who, at the end of the 1960's, began to encounter increasing difficulties in the labor market. Statutory amendments were passed in the early 1970's to change the rules that govern eligibility for disability pensions. It is estimated that a worker earning the average wage receives about 88 percent of prior after-tax income from a government disability pension and, for most workers, there is also a union-negotiated disability pension.[19] So, older workers who leave the labor market in this way maintain their living standards.

While there is much talk in the United States about increasing the age of eligibility for full social security retirement benefits from 65 to 68, Sweden has been going in the opposite direction. In 1976, the pensionable age for full benefits was lowered from 67 to 65, and reduced benefits can be received at age 60. Unlike an American worker, a jobless Swedish worker is not forced to take early retirement with its permanently reduced benefits, because there are no alternative sources of income. The disability pension can maintain income until age 65, when the old-age pension would start.

The most interesting option for an employed worker who wishes to gradually reduce working prior to full retirement is the partial pension system that was introduced in 1976. Partial pensions are geared to part-time work. The rule is that working hours must be reduced by at least 5 hours a week and, after the reduction, must still be at least 17 hours weekly. The worker must also have been employed for at least 10 years after the age of 45. (Because of these rules, the partial pension has been used disproportionately by men.) The partial pension pays 50 percent of the loss of earnings that result from the reduction in hours. However, because of Sweden's high marginal tax rates, the actual disposable income from the combined partial pension *and* part-time earnings is substantial. Unlike early retirement benefits, a partial pension does not result in a smaller pension at age 65. At age 65 a worker can receive a full old-age pension without any retirement test. It is also possible to postpone collecting all or part of the old-age pension. If that is done, the pension will be larger when payments finally start.

The partial pension plan is extremely popular. It provides a bridge between work and full-time retirement. Many people who retired faced a shock—an abrupt change in their way of life after a lifetime of work. They missed their friends and social contacts at work. Doctors and psychologists supported unions in their desire to enable a more gradual transition into retirement. The main argument against disability pensions for the older unemployed worker in Sweden is not based on economics, but is based on the feeling that such pensions lead to social isolation and a self-identification as disabled.[20] The partial pension avoids these problems and also is available to workers not threatened by unemployment. Partial pensions also enable some workers who might not be able to function on a full-time basis to avoid disability pensions. The partial pension increases the individual's freedom of choice about the age and extent of retirement. It does not, however, resolve the problem of those older workers whose jobs are eliminated by a plant closing. One cannot work part time at a nonexistent job. Nor does it resolve the problems of older jobless workers who still have not reached the age of 60. ☐

The Anatomy of Price Change

Reconciling the CPI and the PCE Deflator: 2nd quarter 1982

JULIE A. BUNN AND JACK E. TRIPLETT

This article presents the fifth reconciliation of the Federal Government's two major inflation measures—the Consumer Price Index (CPI), published by the Bureau of Labor Statistics, and the Implicit Price Deflator for Personal Consumption Expenditures (PCE Deflator), produced by the Bureau of Economic Analysis. The first reconciliation, which established the technical basis for the analysis, appeared in the September 1981 *Review* and showed that the divergence between the two price measures could be reconciled in terms of three factors—differences in the measurement of housing costs, differences in "weighting", and the effects of "all other" factors.[1]

Table 1. "Reconciliation" of annual and quarterly percent changes in the CPI-U and the Personal Consumption Expenditure price measures, 1980 to second quarter 1982

Difference	1980[1]	1981[1]	1981[1,2]				1982	
			I	II	III	IV	I	II
CPI-U[3]	13.5	10.4	11.0	7.8	11.8	7.7	3.2	4.6
PCE: Chain-Weight[4]	10.7	9.1	10.3	7.4	8.0	7.2	5.2	3.7
Total difference[5] (CPI-U minus PCE: Chain-Weight)	2.8	1.3	0.7	0.4	3.8	0.5	−2.0	0.9
Housing treatment[6]	2.3	0.9	0.4	0.5	2.7	−0.5	−1.3	1.6
Weighting effect[7]	0.5	0.2	0.6	0.3	−0.4	−0.1	−0.4	−0.4
"All other" effect[8]	0.0	0.2	−0.3	−0.4	1.5	1.1	−0.3	−0.3

[1] Owing to the July 1982 revision of data produced by the Bureau of Economic Analysis, U.S. Department of Commerce, the annual and quarterly figures may differ slightly from those which appeared in table 1, p. 37, July 1982, *Monthly Labor Review (MLR)*.

[2] Seasonally adjusted annual rates.

[3] Annual and quarterly changes in the CPI-U are taken from tables provided by the Office of Prices and Living Conditions, Bureau of Labor Statistics (BLS). The changes are compiled from 1967 based indexes.

[4] Data for the "PCE: Chain-Weight" were obtained from the Bureau of Economic Analysis (BEA), U.S. Department of Commerce.

[5] CPI-U minus "PCE: Chain-Weight" equals the sum of "housing treatment", "weighting", and "all other" effects.

[6] Change in CPI-U minus change in CPI-X1. See September 1981 *MLR*, p. 12, for fuller explanation. Source of CPI-X1 data is same as footnote 3.

[7] Change in "PCE: 1972-Weight" minus change in "PCE: Chain-Weight". See September 1981 *MLR*, pp. 8–9, for fuller explanation. Data source for "PCE: 1972-Weight" changes is same as for footnote 4.

[8] Change in CPI-X1 minus change in "PCE: 1072-Weight". See September 1981 *MLR*, p. 6, for fuller explanation.

Table 2. "Reconciliation" of the CPI-U and the Personal Consumption Expenditure price measures: cumulative percent change from 1972 to the dates shown

Difference	1980	1981	1981[1]				1982	
			I	II	III	IV	I	II
CPI-U (1972 = 100)[2]	197.0	217.4	210.3	214.3	220.4	224.6	226.3	228.9
PCE Deflator (1972 = 100)[3] (Current-Weight)	179.2	194.5	189.2	192.6	196.4	196.8	202.2	204.0
Total difference[4] (CPI-U minus PCE Deflator)	17.8	22.9	21.1	21.7	24.0	24.8	24.1	24.9
Housing treatment[5]	11.7	14.5	13.3	13.7	15.4	15.5	15.3	16.0
Weighting effect[6]	5.6	7.6	7.4	7.6	7.5	7.7	7.7	7.7
"All other" effect[7]	0.5	0.8	0.4	0.4	1.1	1.6	1.1	1.2

[1] Owing to changes in seasonal adjustment factors and to the July 1982 revision of data produced by the Bureau of Economic Analysis, U.S. Department of Commerce, annual and quarterly figures may differ slightly from those which appeared in table 2, p. 38, July 1982, *Monthly Labor Review (MLR)*.

[2] Annual data for the CPI-U are annual averages, 1972=100. The quarterly data for 1981 and 1982 were computed by the Office of Research and Evaluation, employing seasonally adjusted monthly data provided by the Office of Prices and Living Conditions (BLS).

[3] Data for the implicit PCE Deflator, or "PCE: Current-Weight" index, were provided by the Bureau of Economic Analysis, U.S. Department of Commerce. The data incorporate revisions released in August 1982.

[4] CPI-U minus PCE Deflator equals the sum of "housing treatment", "weighting", and "all other" effects.

[5] CPI-U minus CPI-X1. See September 1981 *MLR*, p. 5, for fuller explanation. Data source for the CPI-X1 is the same as footnote 2.

[6] "PCE: 1972-Weight" minus "PCE: Current-Weight". See September 1981 *MLR*, p. 6, for fuller explanation. Data source for the "PCE: 1972-Weight" is same as footnote 3.

[7] CPI-X1 minus "PCE: 1972-Weight". See September 1981 *MLR*, p. 6, for fuller explanation.

As with earlier articles in this series, two different reconciliations are presented, one dealing with period-to-period changes in the price measures, and the other with total movement over the decade from 1972 to date.

Reconciling period-to-period changes. In the second quarter of 1982, the Consumer Price Index for All Urban Consumers (CPI-U) rose more rapidly than the "PCE: Chain-Weight" index.[2] This followed an unusual first quarter in which, for only the second time in 3 years, the reverse had been true. (Compare the first two lines in table 1.)

The renewed acceleration of the CPI-U relative to the "PCE: Chain-Weight" index in the most recent quarter is, however, attributable only to the reemergence of a positive "housing treatment" effect. During the most recent quarter, the CPI-U was once again accelerating at a faster rate than the CPI-X1, the Consumer Price Index which approximates a rental equivalence measure of housing comparable to that employed in the PCE Deflator (the difference between the two being 1.6 percentage

---

Julie A. Bunn is an economist in and Jack E. Triplett is assistant commissioner of the Office of Research and Evaluation, Bureau of Labor Statistics.

points—the "housing treatment" effect).

The other two components of the difference between the CPI-U and the "PCE: Chain-Weight" index—the "weighting effect" and "all other effect"—remain negative and are both identical to their values in the first quarter of 1982. The "PCE: Chain-Weight" index, which draws its weights from the immediately preceding period, continued to rise more rapidly than a fixed weight index (1972=100) based on the same price data,[3] giving rise to the negative "weighting effect" recorded in table 1. The latter, as noted in previous articles, is unexpected and unusual, though it has now persisted for four quarters. Included in the "all other" effect is the influence of different seasonal adjustment procedures followed in the CPI-X1 and the "PCE: 1972-Weight" indexes.

Reconciling cumulative changes. Table 2 updates cumulative comparisons of the CPI-U and PCE Deflator which appeared in previous articles, extending the reconciliation through the second quarter of 1982. Results are complementary to those of the period-to-period reconciliation.

FOOTNOTES

[1] The initial reconciliation and technical basis for the analysis are contained in Jack E. Triplett, "Reconciling the CPI and PCE Deflator," *Monthly Labor Review*, September 1981, pp. 3–15. Subsequent reconciliations appeared in the January, May, and July 1982 issues of the *Monthly Labor Review*.

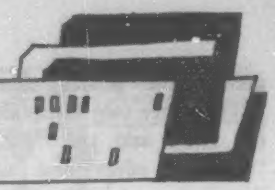
[2] As discussed in Triplett, pp. 7, 13–14, the PCE Deflator, a Paasche-formula index, cannot be used for this reconciliation because Paasche formulas lend themselves to statistical interpretation only when referring back to the base year (in this case, 1972).

[3] See footnote 7 to table 1 and the September 1981 *MLR* article for information on the computation of the weighting effect.

A note on communications

The *Monthly Labor Review* welcomes communications that supplement, challenge, or expand on research published in its pages. To be considered for publication, communications should be factual and analytical, not polemical in tone. Communications should be addressed to the Editor-in-Chief, *Monthly Labor Review*, Bureau of Labor Statistics, U.S. Department of Labor, Washington, D.C. 20212.

Research Summaries



Occupational salary levels for white-collar workers, 1982

MARK S. SIELING

The Bureau of Labor Statistics recently released the results of its March 1982 survey of professional, administrative, technical, and clerical pay in medium and large firms. The survey, 23rd in an annual series, provides nationwide salary averages and distributions for some 100 work level categories covering two dozen occupations.[1] The number of work levels per occupation varied from one for messengers to eight for engineers. Each level describes duties and responsibilities in private industry that are comparable with those of specific groups of Federal white-collar employees. In keeping with the Federal Pay Comparability Act of 1970, the narrowly defined occupational classifications of the survey provide the link between private and Federal Government sectors, thereby permitting compliance with the congressional directive that "Federal pay rates be comparable with private enterprise pay rates for the same levels of work."[2]

Among the various skill levels of white-collar work, salary increases continued to be largest for journeyman and senior levels of professional and administrative occupations. Table 1 shows that Group C jobs—equivalent to grades 11–15 of the Federal Government's General Salary (GS) Schedule—experienced a record 10.4-percent salary rise in 1981–82. Group C pay increases also led those of the two lower groups in 4 of the preceding 5 years. (See table 2 for identification of the survey classifications that equate to each GS grade.[3])

A closer look finds that the pay gap between entry-level professionals and their experienced coworkers widened in the 1970's, as the latter group generally chalked up substantially larger salary increases. The following tabulation illustrates this point by showing pay levels of four journeyman classifications (GS 11 equivalents) as a percent of the corresponding entry levels (GS 5).[4] Note that the journeyman advantage has slipped slightly since 1979:

Table 1. Percent increases in average salaries by work level category, 1970–82

Period	Group A (GS grades 1–4)	Group B (GS grades 5–10)	Group C (GS grades 11–15)
1970–82	130.4	123.0	126.0
1970–71	6.2	6.3	6.2
1971–72[1]	6.3	5.2	6.6
1972–73	5.5	4.4	5.7
1973–74	6.2	5.7	6.2
1974–75	9.1	8.6	8.8
1975–76	7.6	6.4	6.5
1976–77	6.9	6.3	7.7
1977–78	7.5	8.0	8.8
1978–79	7.2	7.5	8.0
1979–80	9.1	10.1	9.3
1980–81	9.8	9.6	10.2
1981–82	9.5	9.4	10.4

[1] Actual survey-to-survey increases have been prorated to a 12-month period.

	1970	*1979*	*1982*
Accountant	150	174	173
Auditor	158	183	179
Chemist	155	176	173
Engineer	144	150	146

In recent years, however, the strong demand for engineers has bolstered their starting salaries, thus keeping the pay gap between their entry and journeyman levels relatively small. This practice is evident when engineer salaries are compared to those of another technical profession—chemist. In 1982, average salaries for entry-level engineers were 20 percent higher than starting chemist salaries; at the journeyman level, in contrast, the difference was only 1 percent (table 2).

The effects of such changes are reflected in the overall salary structure for professional jobs since 1970. Based on a matrix analysis of five professional occupations spanning 30 work levels, the average difference for 435 paired comparisons was 65 percent in 1982 and 58 percent in 1970.[5] How these individual jobs and their work

---

Table 2. Average salaries of employees in selected white-collar occupations in private establishments, March 1982

Occupational level and Federal GS grade equivalent	Number of employees[1]	Average annual salary[2]
Accountants and auditors		
Accountants I (GS-5)	14,291	$16,280
Accountants II (GS-7)	23,570	22,068
Accountants III (GS-9)	35,575	25,673
Accountants IV (GS-11)	21,187	31,658
Accountants V (GS-12)	7,614	38,080
Accountants VI (GS-13)	1,344	46,540
Chief accountants I (GS-11)	654	34,506
Chief accountants II (GS-12)	983	39,708
Chief accountants III (GS-13)	672	50,414
Chief accountants IV (GS-14)	180	61,255
Auditors I (GS-5)	2,498	17,901
Auditors II (GS-7)	3,760	22,086
Auditors III (GS-9)	4,797	26,502
Auditors IV (GS-11)	2,558	32,004
Public accountants I (GS-7)	9,035	17,298
Public accountants II (GS-9)	9,570	19,177
Public accountants III (GS-11)	8,485	22,830
Public accountants IV (GS-12)	4,430	27,286
Attorneys		
Attorneys I (GS-9)	1,878	25,162
Attorneys II (GS-11)	3,008	31,886
Attorneys III (GS-12)	3,622	39,649
Attorneys IV (GS-13)	2,819	49,818
Attorneys V (GS-14)	1,896	61,579
Attorneys VI (GS-15)	707	76,202
Buyers		
Buyers I (GS-5)	6,422	18,074
Buyers II (GS-7)	16,901	22,174
Buyers III (GS-9)	17,561	27,424
Buyers IV (GS-11)	5,449	33,409
Programmers		
Programmers/programmer-analysts I (GS-5)	13,043	17,535
Programmers/programmer-analysts II (GS-7)	30,366	20,629
Programmers/programmer-analysts III (GS-9)	45,970	25,182
Programmers/programmer-analysts IV (GS-11)	26,380	29,365
Programmers/programmer-analysts V (GS-12)	7,950	35,430
Personnel management		
Job analysts I (GS-5)	216	18,573
Job analysts II (GS-7)	444	19,900
Job analysts III (GS-9)	822	25,026
Job analysts IV (GS-11)	524	31,221
Directors of personnel I (GS-11)	1,061	31,136
Directors of personnel II (GS-12)	2,120	38,166
Directors of personnel III (GS-13)	[illegible]58	47,553
Directors of personnel IV (GS-14)	287	57,859
Chemists and engineers		
Chemists I (GS-5)	3,617	19,640
Chemists II (GS-7)	6,677	23,474
Chemists III (GS-9)	10,900	28,016
Chemists IV (GS-11)	11,028	34,047
Chemists V (GS-12)	8,912	40,207
Chemists VI (GS-13)	3,826	46,971
Chemists VII (GS-14)	1,438	53,658
Chemists and engineers—Continued		
Engineers I (GS-5)	31,293	$23,622
Engineers II (GS-7)	60,083	26,060
Engineers III (GS-9)	116,212	29,331
Engineers IV (GS-11)	138,972	34,443
Engineers V (GS-12)	101,701	40,677
Engineers VI (GS-13)	45,853	47,442
Engineers VII (GS-14)	14,102	54,338
Engineers VIII (GS-15)	2,874	62,494
Technical support		
Engineering technicians I (GS-3)	7,170	14,698
Engineering technicians II (GS-4)	20,271	17,246
Engineering technicians III (GS-5)	31,340	20,219
Engineering technicians IV (GS-7)	36,830	23,620
Engineering technicians V (GS-9)	21,651	26,761
Drafters I (GS-2)	3,161	11,739
Drafters II (GS-3)	11,929	14,257
Drafters III (GS-4)	23,277	17,046
Drafters IV (GS-5)	26,149	20,864
Drafters V (GS-7)	20,762	25,909
Computer operators I (GS-4)	6,141	11,896
Computer operators II (GS-5)	14,926	13,695
Computer operators III (GS-6)	29,523	15,804
Computer operators IV (GS-7)	16,252	18,325
Computer operators V (GS-8)	9,212	22,860
Computer operators VI (GS-9)	360	23,287
Photographers II (GS-5)	570	18,773
Photographers III (GS-7)	725	22,425
Photographers IV (GS-9)	434	25,382
Clerical		
Accounting clerks I (GS-2)	27,738	10,478
Accounting clerks II (GS-3)	85,417	12,486
Accounting clerks III (GS-4)	58,870	14,713
Accounting clerks IV (GS-5)	23,519	18,083
File clerks I (GS-1)	22,495	9,018
File clerks II (GS-2)	12,109	10,474
File clerks III (GS-3)	4,037	12,794
Key entry operators I (GS-2)	58,672	11,771
Key entry operators II (GS-3)	40,048	13,956
Messengers (GS-1)	13,931	9,899
Personnel clerks/assistants I (GS-3)	2,353	11,706
Personnel clerks/assistants II (GS-4)	4,083	14,122
Personnel clerks/assistants III (GS-5)	3,576	15,718
Personnel clerks/assistants IV (GS-6)	1,767	18,432
Purchasing assistants I (GS-4)	4,791	13,589
Purchasing assistants II (GS-5)	4,605	17,117
Purchasing assistants III (GS-6)	1,577	22,276
Secretaries I (GS-4)	83,768	14,000
Secretaries II (GS-5)	63,060	14,939
Secretaries III (GS-6)	106,588	17,051
Secretaries IV (GS-7)	45,616	18,803
Secretaries V (GS-8)	22,670	21,546
Stenographers I (GS-3)	15,562	14,867
Stenographers II (GS-4)	11,534	18,094
Typists I (GS-2)	31,703	10,893
Typists II (GS-3)	17,822	13,723

[1] Occupational employment estimates relate to the total in all establishments within scope of the survey and not to the number actually surveyed.

[2] Salaries reported relate to the standard salaries that were paid for standard work schedules; i.e., the straight-time salary corresponding to employee's normal work schedule excluding overtime hours. Nonproduction bonuses are excluded, but cost-of-living bonuses and incentive earnings were included.

NOTE: The following occupational levels were surveyed but insufficient data were obtained to warrant publication: Chief accountant V; director of personnel V; chemist VIII; personnel clerk/assistant V; engineering technician VI; and photographer I and V.

levels fared in salary increases over the 1970–82 period is shown below:

	Percent increase		
	Level I	*Level II*	*Average for remaining levels*
Accountant	115	130	146
Attorney	112	133	139
Auditor	101	122	131
Chemist	114	129	137
Engineer	131	135	141

Although the salary structure widened, it left the relative ranking of professional work levels by pay virtually unchanged. Only 2 (Attorneys I and II) of 30 moved more than one position between 1970 and 1982.

In 1982, the survey's highest professional salary average was for top-level (VI) corporate attorney at $76,202 a year; the lowest-paid professional classification—entry-level (I) auditor—averaged $17,901 (table 2). These extremes reflect the wide range of duties and responsibilities represented by all professional categories covered by the survey. In contrast, the typical salary spread among job categories with equivalent levels of work is relatively narrow. Thus, annual average salaries for the six work levels surveyed that equate to Federal GS grade 13 ranged from $46,971 for chemist VI to $50,414 for chief accountant III[6]—a difference of only 7 percent. Salary relationships produced by the survey are evidence that companies recognize equivalent duties and responsibilities among a wide range of occupations within broad categories.

Another characteristic of white-collar workers reported in the survey is the pronounced variation in their earnings within occupational work levels. Salaries of the highest paid employees in a single work level were commonly twice those of the lowest paid employees. Consequently, some professional workers in the first journeyman level earned as much as, or more than, their counterparts in more senior levels; for example, 10 percent of accountants III and 7 percent of accountants V earned between $30,000 and $32,500 annually in March 1982. Factors contributing to dispersed salaries include such traditional wage determinants as firm size, industry, and geographic location in addition to range-of-rate plans used by many employers to recognize merit or seniority.

A MORE DETAILED ANALYSIS of white-collar salaries and complete results of this year's survey are contained in the *National Survey of Professional, Administrative, Technical, and Clerical Pay, March 1982*, BLS Bulletin 2145, September 1982. It includes salary distributions by occupational work level, and relative employment and salary levels by industry division for the two dozen occupations studied. ☐

FOOTNOTES

[1] The survey is conducted annually with a March reference period in metropolitan areas and nonmetropolitan counties in the United States, except Alaska and Hawaii. Metropolitan areas accounted for nine-tenths of the employees in occupations for which salary data were developed.

[2] 5 U.S.C. Sec. 5301(a)(3)(1970). The pay-setting role of the Professional, Administrative, Technical, and Clerical Survey is described in George L. Stelluto, "Federal pay comparability: facts to temper the debate," *Monthly Labor Review*, June 1979, pp. 18–28.

[3] In 1982, a total of 101 work levels produced publishable data out of the 108 levels within scope of the survey. Of these 101 work levels, 92 were sufficiently unchanged in definition between the 1981 and 1982 surveys to be used in computing the 1981–82 increases shown in table 1. Widely varying duties and responsibilities may be embodied in work levels within each of the broad categories of table 1; for example, Group B includes journeyman, clerical, and technical levels, such as accounting clerk IV and engineer technicians III through IV, as well as the entry and developmental levels of professional occupations.

[4] A similar pattern was found for the 1970's in the salary relationship of recent law graduates with bar membership (survey job attorney I) and attorneys with experience handling legal work with few precedents (attorney III)—GS grade equivalents 9 and 12, respectively. The salary relatives were 142 in 1970 and 158 in 1979 and 1982.

[5] The pay matrix helps to analyze the comparative salary position of each job classification with each of its counterparts. The matrix expands upon the traditional approach which limits comparisons of occupational averages to the highest and lowest levels or to setting a single job as the base for all others to be measured against. The difference between the resulting means of the paired comparisons in 1970 and 1982 was statistically significant at a 5-percent level. For a description of the matrix and its use, see Mark S. Sieling, "Interpreting pay structures through matrix applications," *Monthly Labor Review*, November 1979, pp. 41–45.

[6] In the survey coding structure, the level designations among various occupations are not synonymous: For example, the first level of attorneys equates to the third levels of accountants, chemists, and most other professional and administrative occupations. See table 2 for more details on job level equivalents. Classification of employees in the occupations and work levels surveyed is based on factors detailed in definitions which are available upon request.

Employment Cost Index continues to decelerate in second quarter

The Employment Cost Index (ECI), measuring changes in employer compensation costs, increased 1.1 percent in the 3 months ended in June. Wages and salaries alone rose 0.9 percent. The index stood at 107.5 for compensation costs (wages, salaries, and employer costs for employee benefits) based on June 1981 = 100. The ECI does not cover farm, private household, and Federal government workers and is not seasonally adjusted.

The deceleration in rates of increase for both compensation costs and for wages and salaries alone that began in 1981 continued to be widespread among occupational and industrial groups measured by the ECI. Compensation costs for all private nonfarm workers slowed to a 1.3-percent rise in the second quarter, down from 1.9

percent a year earlier. The corresponding wage and salary increase, 1.1 percent, was down from 2.0 percent a year earlier.

Workers in occupations and industries that typically receive the bulk of their wage adjustments in the second quarter showed relatively small gains. Transport equipment operatives, for example, posted a 0.9-percent wage increase. The advance was dampened by the recent trucking industry bargaining settlements that provided no specified wage increases and diverted part of the cost-of-living adjustment to maintain existing employee benefits. Over the past 5 years, second-quarter wage increases for transport equipment operatives ranged between 3 and 5 percent.

Wages for workers in the construction industry rose 1.3 percent in the second quarter—an unusally low increase for an industry with a heavy bargaining schedule in the spring and summer months. Second-quarter wage increases in construction ranged between 2 and 3 percent over the past 5 years.

A substantial deceleration in rates of increase in compensation costs and wages and salaries for the year ended in June 1982 compared with the preceding year also occurred. A particularly dramatic slowdown occurred in compensation cost increases for blue-collar workers in private industry. These costs slowed to a 7.0-percent increase in the year ended in June 1982, from a 10.5-percent rise in the year ended in June 1981. Wage increases alone for these workers slowed to 6.6 percent, down from 9.2 percent a year earlier.

Among white-collar workers, compensation costs rose 7.2 percent for the 12 months ended in June 1982 compared with 10.2 percent during the year ended in June 1981; their wages and salaries increased 7.3 percent, down from 9.4 percent in June 1981. Rates of change within the white-collar group varied substantially, however. Salesworkers' wages, which include volatile commission earnings, rose only slightly, 1.8 percent, for the June 1981–82 period in contrast to 10.2 percent for June 1980–81. However, wage increases for clerical workers, 8.3 percent for the 12 months ended in June 1982, were only slightly below the June 1981 advance of 8.8 percent.

Compensation costs for union workers rose 8.4 percent in the June 1981–82 period, contrasted to 11.5 percent a year earlier; union wage and salary increases dropped to 8.1 percent from 10.1 percent.

The slowdown was also evident for nonunion workers. Compensation costs increased 6.5 percent for the 12 months ended in June, down from 9.8 percent a year earlier; wage increases were 6.5 percent and 9.0 percent.

Compensation costs for State and local government employees, coverage introduced in June 1981, increased 9.3 percent over the year. Wages for these workers advanced 8.7 percent.

Additional data on second-quarter ECI results appear in the Current Labor Statistics section of the *Review*. ☐

GAO study focuses on problems of teenagers in labor market

Teenage unemployment, especially that of blacks, has been a concern among policymakers in recent years. According to the General Accounting Office (GAO), unemployment among black teenagers had increased sharply since 1970—along with a coincident rise in crime among all teens.

During 1949–80, the unemployment rate of white male teenagers stayed about three times higher than that of adult males. However, a substantial amount of the difference in these rates can be traced to teens voluntarily leaving jobs and the labor force.

Of all teenagers, those who are unemployed represent only a fraction; but this relatively small group is largely composed of poor and black persons. Therefore, high unemployment indicates a serious labor market problem for black teenagers.

GAO found that using labor force and employment status as the major criteria for ascertaining the need for teenage employment services was insufficient. Many teenagers lack the basic reading, writing, and computation skills required to compete and succeed in the job market, the congressional agency reported. Therefore, using a detailed analysis of the educational achievement, labor force status, and demographic characteristics of teens, GAO estimated that in 1977 "approximately 962,000 economically disadvantaged teenagers (16 to 21 years old) with a high school degree or lower attainment [were] most in need of Federal assistance." In subsequent years, the number in need depends on how long the average person needs assistance.

Since 1940, there have been extensive racial differences in teenage unemployment outside the South. From 1940 to 1950, nonwhite unemployment was lower in the South than white unemployment during the same period. However, since 1970, the difference has widened significantly in all U.S. regions.

GAO cities two major unresolved questions—why did the black teenage unemployment rate rise so sharply since 1970 and what are the underlying factors of the large and persistent (40 plus years outside the South) teenage unemployment difference? The study finds the most important reasons to be lower scholastic achievement, which, in turn, is a function of many family background variables, and inaccessibility to job vacancy information.

Factors which caused the racial dissimilarities in teenage labor participation were difficult to find. A partial explanation appears to be discouragement. Teenagers, who lack the personal qualifications necessary for a job, may have had a few bad employment experiences and then decided to withdraw from the labor force, discouraged over their predicament.

Some additional evidence on this issue is provided by an analysis of other possible causes. It shows that nearly three-fourths of the racial difference in labor force participation of out-of-school teens is explained by family background. The analysis also suggests that black teenagers living in households receiving Aid for Families with Dependent Children since 1960 may have been a cause of the relative worsening of labor force participation and unemployment rates among young blacks in recent years.

The claim that a teenager's inability to find a job can have an effect on his or her inclination to commit a crime seems plausible, the GAO study states. However, evidence on the causes of crime does not show how important the effect of unemployment is. Some studies suggest that it may be important, but they are flawed statistically and those that do not have these flaws deal with problems other than unemployment.

Inability to find a job is not the only factor potentially contributing to crime. Being unable to qualify for a job would logically seem much more conducive to criminal behavior, but, because of insufficient data, GAO has not been able to analyze this group. Regardless of a link to crime, teenagers unqualified for jobs are a serious social problem, GAO noted.

Considering the effect of low wage jobs versus unemployment may also be important. A "job-qualified" teenager might not be driven to crime by a moderately difficult period of unemployment, but, depending on aspirations, the prospect of a lifetime of very modest paying jobs might make crime attractive, according to the study.

On the bright side, GAO could find no evidence that being out of work occasionally as a teenager has any adverse effect on future labor market opportunities or successes. This held true even for out-of-school teenagers.

The GAO report concludes that studies should be conducted to find new ways of identifying and delivering education and training services to disadvantaged teens. Also, the agency believes that extended research is necessary on the link between teenage unemployment and crime. However, the study notes that the Department of Labor disagrees with both suggestions.

The full report, *Labor Market Problems of Teenagers Result Largely from Doing Poorly in School*, Washington, D.C., March 1982, (PAD-82-06), is available from the U.S. General Accounting Office, Document Handling and Information Services Facility, Gaithersburg, Md. 20760. □

Foreign Labor Developments

Political issues dominate ILO conference; new worker standards adopted

JULIE MISNER

The International Labor Organization (ILO), which this year had grown to number 150 member states, held its 68th general conference in Geneva, Switzerland. Alfonso Grados Bertorini, labor minister from Peru, was elected conference president. Although the conference adopted a number of new international labor standards, its deliberations were dominated by political issues, according to members of the U.S. delegation.

Founded in 1919, the ILO is unique among the United Nations' specialized agencies because of its tripartite structure. Worker and employer delegates enjoy equal and independent representation with governments. The ILO's mission is to promote employment, better working conditions, and worker and employer rights. Its tools include an annual conference, smaller technical meetings, research, and technical cooperation.

From the outset, all the elements were present to make the June 2–23 conference a political arena—the Israeli invasion of Lebanon, the Argentine-British hostilities in the Falkland Islands, apartheid, Poland, and the Iran-Iraq war. In reaction to these developments, some delegates used the conference plenary sessions to make political denouncements, often insulting other member states and straying far from the competence of the ILO conference. Other delegates, including those of the United States, reminded the conference of the one political issue germane to and at the very heart of the ILO: freedom of association. These participants lamented the renewed and heightened challenges to the principles of freedom of association and the unfortunate absence of Poland's Lech Walesa, who had participated in the 1981 conference—to the cries of "political interference" from Communist delegates.

The same political undercurrents were present—although usually unstated—in the technical work of the conference and during the special visits by French President Francois Mitterand and Pope John Paul II. But it was in three committees, which by their mandate and makeup were politically charged, that most of the drama of the conference developed: the Resolutions Committee, the Committee on the Application of Conventions and Recommendations, and the Committee on Apartheid.

Resolutions deadlock

Because it considers proposals unrelated to any item on the conference agenda, the Resolutions Committee is always a prime target for excessive and extraneous politicization. In theory, resolutions should deal with technical labor issues and propose new areas for ILO program emphasis. In practice, such resolutions are usually overshadowed by politically inspired resolutions having little to do with the ILO.

This year's Resolutions Committee was so beset by chaotic procedural wrangling (including one session adjourned because of a bomb threat and another adjourned following an almost total breakdown of order) that it ended in a deadlock. Not only were no resolutions forwarded to the conference plenary for adoption, but the committee was unable to adopt a report describing its work. Nevertheless, after 2½ weeks of chaos in committee, the anticipated blowup when the "non-report" reached the plenary never materialized.

Eighteen draft resolutions were submitted to the conference secretariat prior to the May 18 deadline (that is, 15 days before the opening of the conference, as required by ILO rules). The most potentially difficult and explosive of these was an Arab resolution concerning "The Observance of a Day of Solidarity with the Workers and People of Palestine, the Golan and the other occupied Arab Territories."[1]

The Arab bloc and its allies joined the committee in unprecedented numbers to ensure adoption of the resolution, but when results of the secret ballot for the five priority resolutions were announced, the Arab resolution—for the first time in almost 10 years—had not taken first place. The committee had decided to consider the draft resolutions in the following order:

- Freedom of association
- Arab resolution concerning Palestinian workers

Julie Misner is a program analyst in the Office of International Organizations, Bureau of International Labor Affairs, U.S. Department of Labor.

- Employers' group resolution on possible ILO funding of conference delegations
- Sudanese resolution on African refugees
- ILO participation in the International Youth Year

This meant that the discussion on the freedom of association resolution—which contained language unacceptable to the Soviet bloc—would have to be completed before the committee could consider amendments to the Arab resolution. What ensued, according to many knowledgeable participants and observers, was an apparently calculated disruption and blockage of the committee's proceedings, and the ultimate failure of the committee to agree on anything. Following a general discussion of the first three resolutions, the committee never progressed beyond the first 5 of 71 amendments to the freedom of association resolution. In its last sitting, the committee was even unable to adopt a report describing its lack of progress.

On the final day of the conference, the President noted the absence of a Resolution Committee report and concluded that there was, as a result, nothing to discuss. His statement, to the great surprise of many delegates who anticipated a major confrontation sparked by the Arabs' failure to win passage of their resolution, went unchallenged, and the conference quietly proceeded to the next item of business. However, the toll had already been taken the day before on the report of the Committee on the Application of Conventions and Recommendations.

Poland criticized

The Committee on the Application of Conventions and Recommendations faced a particularly difficult task this year, with 115 cases concerning approximately 70 countries. Among the politically sensitive cases on the agenda were Poland, the Soviet Union, Cuba, Czechoslovakia, Argentina, Nicaragua, Chile, and Bolivia. Coupled with the sheer number of cases to be examined, as well as the sensitive nature of some of them, were the emotional tensions surrounding the Israeli invasion of Lebanon and the clear disregard for the whole process of standards supervision on the part of the Eastern bloc.

Despite its frequently electric atmosphere, the Committee on the Application of Conventions and Recommendations for the most part continued to successfully use its new methods of work (that is, a new special list system for highlighting both cases of progress and problems in implementing standards) adopted in 1980. This system includes a heading called "continued failure to implement," in which are listed governments which violated ratified ILO standards for a number of years and have failed to cooperate with ILO efforts to bring their law and practice into line. This is the ILO's most serious form of censure.

In the committee's report, Chile was cited for "continued failure to implement" Convention 111 concerning discrimination in employment—in this case dismissals of persons from the public service because of their political opinions. The governments of Bolivia and Burma were highlighted in special paragraphs for their problems in implementing Convention 87 on freedom of association.

But it was the case of Poland which took and maintained center stage throughout the proceedings of the Committee on the Application of Conventions and Recommendations, both in terms of the substance of discussion as well as the influence it exerted over the subsequent work of the committee. The Government of Poland came under the scrutiny of the committee for its violations of freedom of association stemming from its December 1981 declaration of martial law and imprisonment of hundreds of Solidarity leaders and members—this immediately following a separate examination on the same subject by the Governing Body's Committee on Freedom of Association. Although the Polish government initially expressed its willingness to cooperate with the ILO's supervisory machinery, it reversed its position when the committee recommended that the case be highlighted in a special paragraph—even going so far as to call for a vote on that part of the committee's report. (The committee in its conclusions commended the Polish government's recent efforts and progress, but nevertheless expressed its deep concern regarding the infringements of Convention 87 and associated itself with the very strong recommendations of the Committee on Freedom of Association.)

Following some discussion as to whether such a vote could be taken—that is, after the set of conclusions had already been accepted by the committee—a vote by show of hands resulted in the adoption of the special paragraph. One week later, the committee unanimously adopted its full report. However, those who believed that the subject of Poland had been laid to rest were quite surprised when the committee report reached the plenary.

In plenary, just as conference President Alfonso Grados was about to move that the report of the Committee on the Application of Conventions and Recommendations be adopted by consensus, a delegate from the Soviet bloc took the floor to protest the special paragraph on Poland and requested that the report as a whole be put to a vote by the conference. What ensued were two successive votes (first a show of hands, then a record vote the next morning) which prevented the report from being adopted by lack of a quorum—although by a very narrow 8-vote margin.

A breakdown of the record vote on the Committee on the Application of Conventions and Recommendations report revealed that many Arab delegates had joined the Soviets to prevent a quorum from being obtained, at least partly because of their frustration over the events in the Resolutions Committee. Only twice before, in 1974 and 1977, has the conference similarly failed to adopt such a report. While the failure to adopt was disappointing, several delegates made powerful statements—starting with the U.S. Government—commending the work of the committee, supporting the other aspects of the ILO's machinery for the supervision of international labor standards, and pointing out that the conference's failure to adopt the report did not affect the ILO's continued scrutiny of events in Poland.

Conclusions on apartheid questioned

The stated task of the newly established permanent Committee on Apartheid was to review the Director-General's report on the application of the June 1981 "Declaration Concerning the Policy of Apartheid" in South Africa, which contained information on efforts to eliminate apartheid. The information had been submitted by governments and workers' and employers' organizations since adoption of the declaration. The committee's six sessions consisted primarily of a series of speeches denouncing apartheid and calling for measures—mostly economic—to combat it. Its conclusions outlined a number of recommended steps to be taken by governments and the private sector to reduce or eliminate economic relations with South Africa, including supplying information on foreign companies with investments in South Africa, and providing direct assistance to national liberation movements.

Both in the committee and in plenary, a significant minority of government and employer delegates, including those of the United States, stated that while they abhorred apartheid, they found unacceptable the conference's tendency to disregard the ILO's established procedures for due process and to take the organization "beyond its appropriate mandate and competence." The committee's conclusions took note of the reservations expressed by these members, and the anticipated, heated plenary discussion of the apartheid report never came to pass. The report was adopted without vote and without incident.

New labor standards adopted

The 1982 conference considered four technical agenda items. Two items resulted in the adoption of new Conventions and Recommendations, one in the minor revision of an existing Convention; the remaining item will undergo final discussion at the 1983 conference.

An ILO Convention is an international treaty that carries a legal obligation under international law for states which ratify it. A Recommendation, on the other hand, is simply what the name implies—a document which suggests specific measures that can be taken to implement labor policies. Recommendations are not subject to ratification and therefore bear no legal obligation.

Termination of employment. The conference adopted both a Convention and a Recommendation concerning the termination of employment at the initiative of the employer, updating a 1963 Recommendation. At the end of last year's discussion of this item, workers and employers had been diametrically opposed on virtually every point of the proposed standards, with governments divided according to their law and practice. The major controversy surrounded the amount of government regulation that is necessary and appropriate to protect workers against arbitrary and unfair dismissal.

This year the committee remained controversial and at times confrontational, but a small worker-employer working group did successfully propose shifting some of the more objectionable provisions from the Convention to the Recommendation and otherwise moderate the former. Nevertheless, the employers and a number of governments, including the United States, contended that the Convention adopted by the conference still relies too heavily on government intervention and too little on private initiative. As a result, they argued that the instrument is not sufficiently flexible and universal to be widely ratified and implemented.

Social security for migrant workers. The conference also adopted a new Convention (actually a revision of a 1948 Convention) concerning the social security rights of workers and family members who are employed outside their home countries. The new standard extends coverage to all forms of social security and opens the way for applying social security standards to self-employed persons as well as to salaried employees. Most of the provisions of the Convention would take effect as a result of bilateral or multilateral agreements between governments, though some provide for direct and immediate application as a consequence of a member state's ratification of the instrument.

Although U.S. legislation is not completely compatible with the provisions of the new Convention, and U.S. ratification is thus not likely in the foreseeable future, the entire U.S. delegation was able to support adoption of the instrument. The Convention was adopted in an overwhelming affirmative vote by the conference.

Next year, the conference will take up an unprecedented third discussion of the social security issue. This discussion, preceded by a tripartite meeting of social security experts, will formulate model provisions designed for bilateral and multilateral international social security agreements. These provisions will take the form of a Recommendation to supplement the new Convention.

Vocational rehabilitation. The 1982 conference held a general discussion which will lead to the possible adoption in 1983 of a Recommendation supplementing the Vocational Rehabilitation (Disabled) Recommendation of 1955. While the provisions of the original instrument are still relevant, new developments in the field have made it necessary to broaden its scope by updating and expanding its definitions of the terms "vocational rehabilitation" and "disabled." The conference did not accept the ILO secretariat's proposal to include among disabled persons the socially maladjusted, but proposed coverage in the revised instrument for all individuals whose prospects of securing and retaining suitable employment are substantially reduced as a result of "an impairment of a physical, mental, or psychological nature duly recognized by a competent authority."

During the committee's discussions, the workers' group unsuccessfully proposed that the supplementary standard on vocational rehabilitation should take the form of a Convention. While the committee's draft conclusions were easily adopted both in committee and in plenary, the workers are expected to rekindle their call for a Convention next year.

Revision of the Plantations Convention. In the shortest and quietest technical discussion in ILO history, the conference easily adopted a protocol revising Article One of the 1958 Convention concerning the Conditions of Employment of Plantation Workers. The objective of the revision was to limit the ILO's very broad definition of the term "plantation" and thereby pave the way for wider ratification and implementation of the instrument. There was no substantive discussion of conditions of work on plantations.

The revision of the Plantations Convention marks the first time that the protocol format has been used by the ILO conference. The new procedure eliminates the need for publishing an entire new text (only 1 article of 99 was changed) with a new number. In the future, governments will have the option of ratifying either version of the Plantations Convention.

Other work of the conference

In the Conference Finance Committee, which is composed only of government members, contributors to the ILO began—at the initiative of the United States—to take a closer and more critical look at the ILO's growing practice of using supplemental budget requests to finance so-called "unforeseen" expenditures, that is, in excess of the organization's biennial program and budget.

The Structure Committee, on the other hand, accomplished little more than to call for the reconstitution and resumption of the Working Party on Structure (now in its 9th year) and to request that an item on structure be included in the 1983 conference agenda. The structure question involves, among other things, proposed changes in the size and composition of the ILO's Governing Body and its relationship to the conference. Although some of the issues have been ironed out, the structure question is being considered as a "package" and nothing can be resolved until complete agreement is reached. □

Canadian legal approaches to sex equality in the workplace

HARISH C. JAIN

During the last several decades, labor market discrimination against women has become a matter of considerable social and political concern. The rising female labor force participation rate over the years and its projected further increase render this issue even more important.[1] This type of discrimination can take conceptually two forms: employment discrimination and pay discrimination. The former can be defined as unequal job levels for men and women with similar qualifications, and the latter as unequal pay for men and women who have equal qualifications and are performing similar jobs, jobs of equal value, or both (that is, comparable worth).[2]

In this report, equal employment and equal pay legislation are discussed; then, selected cases decided by courts and boards of inquiry are analyzed; and finally, conclusions and policy implications are presented.

Public policy

Equal pay. All Canadian jurisdictions have laws which require equal pay for equal work within the same establishment, without sex discrimination. These provisions have been incorporated either in human rights legislation (Federal jurisdiction, Alberta, British Columbia, New Brunswick, Newfoundland, Northwest Territories, Prince Edward Island, and Quebec) or in labor standards legislation (Manitoba, Nova Scotia, Ontario, Saskatchewan, and Yukon Territory).

Harish C. Jain is a professor of personnel and industrial relations, McMaster University, Hamilton, Ontario, Canada.

At the Federal level, equal pay legislation was first put into effect in 1956 and amended in 1967. It required equal wages for men and women performing the same or similar work under the same or similar working conditions on jobs requiring the same or similar skill, effort, and responsibility. This legislation remained in effect until 1977, when it was replaced by the Canadian Human Rights Act embodying the equal value principle. According to the act, men and women performing work of equal value (regardless of whether the work is similar) must be paid equal wages. The act also elaborates on how the value of work may be assessed; section 11 (2) specifies that in assessing the value of work performed by persons employed in the same establishment, the criterion to be applied is the composite of skill, effort, and responsibility required in the performance of the work and the conditions under which the work is performed. The Quebec legislation calls for equal pay for equivalent work.[3]

Compared with the Federal and Quebec jurisdictions, the various provincial jurisdictions follow a narrow definition of equal work, such as "same work," "similar work," or "substantially the same work." In 6 of the 12 jurisdictions (Ontario, Nova Scotia, New Brunswick, Newfoundland, Prince Edward Island, and Saskatchewan), legislation also specifies factors on which equality of work may be based. These factors are education, skill, experience, effort, responsibility, and working conditions.

The legislation in a majority of jurisdictions provides for a general exception permitting differentials between the pay of men and women based on any factor other than sex. Other jurisdictions list specific exceptions which include seniority, work experience, and merit.

Several court decisions have helped to provide a more precise interpretation of equal pay legislation in Canada.[4] In the Greenacres Nursing Home case in 1970, the Ontario Court of Appeal ruled that "the same work" did not necessarily imply "identical work" and that job comparisons should be based on work performed rather than on formal job descriptions or terms of employment. In the Riverdale Hospital Case in 1973, the concept of equal work was further broadened. Here, the Ontario Court of Appeal ruled that different job titles do not necessarily indicate different work, slightly different job assignments do not make the work unequal, and within an occupation, if some men do the same work as women, equal pay is justifiable for the whole occupation. The last point was clarified in a case in which the Saskatchewan Court of Appeal declared that even when only 5 of 46 male caretakers performed work similar to female cleaners, it should be considered a sufficient number within the provincial equal pay legislation, and that "some" employees being paid a rate of pay higher than others doing similar work warrants equal pay.[5]

The courts have also dealt with what might properly constitute "a factor other than sex" in justifying male-female pay differentials. In two decisions at the Federal level—the C.T.V. Television Network case in 1975 and the La Societe Radio-Canada case in 1977—the Court ruled that differences in the quality of work as assessed by management are sufficient to justify unequal pay. The Court acknowledged that such an assessment might be subjective and, thus, might involve an error of judgment; however, the Court held that it was not within the competence of the judiciary to review management's judgment. The courts have also ruled on whether the existence of two separate bargaining units could be considered "a factor other than sex" to permit pay differentials between them. The Alberta Court of Appeals in the Gares case in 1976 decided against it.[6]

Equal employment. As in the case of equal pay, all jurisdictions in Canada have also enacted human rights legislation. All the statutes prohibit discrimination on the basis of race, national origin, color, religion or creed, sex, marital status, and age. The age groups protected vary among jurisdictions, with the most common being between the ages of 40 or 45 and 65. Discrimination due to physical disability is proscribed in seven jurisdictions. Other prohibited grounds include sexual orientation in Quebec and pardoned offenses in the Federal jurisdiction.[7] These statutes apply to employers, employment agencies, and trade unions. Discrimination is prohibited with respect to advertising and terms and conditions of employment including promotion, transfer, and training.

Indirect or systemic discrimination. Both direct[8] and indirect employment discrimination is prohibited. The Canadian Human Rights Act, as well as numerous decisions by boards of inquiry in several provinces, has borrowed the concept of indirect discrimination from U.S. case law and relevant British legislation, that is, the Race Relations Act and the Sex Discrimination Act.

In the United States, the concept was articulated by the Supreme Court in *Griggs v. Duke Power Co.* in 1971. The Court unanimously endorsed a results-oriented definition of what constitutes employment discrimination and indicated that intent does not matter; the consequences of an employer's actions determine whether it may have discriminated under Title VII of the Civil Rights Act.[9]

Enforcement. In the enforcement of both the equal pay and equal employment legislation, the method common to all jurisdictions is investigation based on employee complaints. (Although, sometimes, Human Rights Commissions may file a complaint or commence an investigation.) All the acts provide for the settlement of complaints, if possible, by conciliation and persuasion and for an initial, informal investigation into a complaint by an officer who is directed to effect a settlement. If conciliation fails, a board of inquiry is usually appointed; it may issue orders for compliance, compensation, and so on. This order may be appealed to the Supreme Court of the Province on questions of law, fact, or both. The Federal jurisdiction allows an appeal by either the complainant or defendant to a review tribunal, if the original tribunal had fewer than three members.[10] In practice, the emphasis has been to concentrate on effectuating a satisfactory settlement rather than legal guilt.[11]

Analysis of cases

Methodology. In order to study the incidence of pre- and post-employment sex discrimination, 52 board of inquiry and court cases were analyzed.[12] These were all the cases that were adjudicated by boards of inquiry, and in some cases by courts, from 1975 to 1980, in Alberta, British Columbia, New Brunswick, Nova Scotia, Ontario, and Saskatchewan. (To our knowledge, no relevant cases were decided by either boards or courts in other jurisdictions.)

Although the bulk of a typical human rights commission's workload consists of cases that do not go to a board, the data on, for example, conciliated cases or cases under investigation are confidential and, therefore, are not analyzed.

The cases covered a cross-section of industries and institutions and were not confined to blue-collar or lower level white-collar workers; professional, technical, and to some extent administrative and managerial workers were also involved. A majority of the cases involved secretarial workers (38 percent) and unskilled laborers (21 percent).

Pre- and post-employment discrimination cases. Pre-employment discrimination cases decided by selected boards of inquiry include allegations regarding male-female job stereotypes, height and weight restrictions, refusal to interview female applicants, sex not being a bona-fide occupational requirement, discriminatory job interviews, and discriminatory job advertisement.

Decisions of boards of inquiry have prohibited such pre-employment barriers as height and weight requirements for a police constable's job,[13] and for jobs requiring physical strength;[14] discriminatory or sex stereotyped questions in job interviews;[15] and employers' misconceptions and stereotypes about traditionally male or female jobs such as not considering: a woman for the job of a cost accountant trainee,[16] a man for the position of a copywriter,[17] a woman as a rental clerk for a rental truck agency,[18] and a woman for heavy-duty janitorial work.[19]

A bona-fide occupational qualification exemption with respect to sex discrimination has been very narrowly construed by the boards. Employers' arguments such as: work being too strenuous for a woman,[20] customer preference for service from either a man or a woman,[21] restaurant atmosphere is created by having all female waitresses,[22] lack of restroom facilities for women,[23] and male-dominated and remote worksite,[24] have been rejected by boards of inquiry in several jurisdictions.

Post-employment discrimination cases deal with casual workers denied full-time jobs; promotion; dismissal; reemployment; pregnancy; and sexual harassment.

Casual to permanent employment. At least three boards of inquiry in Saskatchewan,[25] New Brunswick,[26] and Ontario[27] have dealt with complaints from women regarding their attempt to switch from part- to full-time permanent jobs with the same employer. In these cases, the boards of inquiry held against the employers for denying women permanent positions because of their sex.

Pregnancy. In British Columbia, the "reasonable cause" provision of the Human Rights Code has had a major impact in broadening the scope of prohibited grounds of discrimination that otherwise would have been excluded.[28] In one case, a British Columbia board of inquiry ruled that a woman who was fired from her job as a reservation clerk, when she told her employer that she was pregnant, had been discriminated against.[29] In another case, a board of inquiry allowed sick leave benefits to teachers absent from employment for sickness caused or aggravated by pregnancy, under the "reasonable cause" provision.[30]

Sexual harassment. In a precedent-setting decision, an Ontario board of inquiry declared in August 1980 that sexual harassment is discrimination based on sex, according to section 4(1) of the Human Rights Code. In this case, *Anna Korchzak and Cherie Bell v. Ernest Lada and the Flaming Steer House Tavern, Inc.*, the complainants had alleged that they had been sexually harassed by their employer, the owner of the restaurant. Although the complainants lost, Board Chairman Owen Shime declared that ". . . there is no reason why the law, which reaches into the work place so as to protect the work environment from physical or chemical pollution or extremes of temperature, ought not to protect employees from negative psychological and mental effects where adverse gender-directed conduct emanating from a management hierarchy may reasonably be construed to be a condition of employment." Thus, sex as a prohibited ground of discrimination includes sexual harassment where because of a worker's sex some term or condition of employment is modified by the sexual harassment.[31]

Indirect or systemic discrimination. In 7 of the 52 cases, systemic discrimination was found. An analysis of these cases revealed that the approach adopted in the *Griggs* case, which was previously mentioned, has now been widely emulated in Canada; malice or intent to discriminate is no longer a relevant factor. For example, in a case involving a female applicant, the board decided that the Commission's minimum height requirement of 5 feet, 10 inches "virtually eliminates women as police constables," as only 5 percent of Canadian women are that tall.[32]

Remedies ordered. In most cases in which discrimination was found and that went before a board of inquiry, more than one remedy was ordered. The most frequently given one was compensation for lost wages; the other remedies (in order of frequency) were orders to employers to:

- display the relevant human rights code in predominant places in employer premises;
- stop their unlawful conduct;
- compensate for general damages;
- compensate for expenses incurred by the complainant;
- compensate for pain and humiliation suffered by the complainant;
- reinstate the complainant;
- send a letter of apology to the complainant;
- offer employment or interview at the next available opening;
- have the relevant human rights commission conduct a human rights workshop for company executives;
- amend application form or other selection tools, or both;
- send a letter of apology to the relevant human rights commission; and
- provide separate facilities for women.

Conclusions

The cases discussed in this report seem to indicate that entry and training requirements should be carefully established and maintained only if they are necessary prerequisites for employment and promotion. Therefore, employers should develop clear equal opportunities policies to ensure that they are not discriminating by default of appropriate action and to give themselves some safeguard in case their policies are challenged. For instance, organizations must issue explicit instructions regarding the employment interview through their personnel departments. Interviews should be structured and only questions of direct relevance to the job should be asked.

Organizations should keep in mind that, over the years, substantial evidence of validity has accumulated for many of the predictors. When comparing employment tests, ability tests and work sample tests—relative to personality and interest tests—have proved the most valid. References, recommendations, and interviews usually have been found to be less valid as predictors of job success.[33] Choices of predictors to be used in staffing systems should be governed by the nature of the job, and the validity of the predictors. Staffing systems can be improved considerably by standardization (to obtain reliable information), and by the validation process. Emerging research evidence seems to indicate that validity of tests need not be specific to the situation.[34]

There would appear to be three broad types of human resource policies which might be used to assist minority workers.[35] First, taking labor supply and demand as given, one might attempt to make the labor market operate more efficiently by means of placement activities, worker counseling, and labor mobility or related measures, which would be appropriate regardless of the labor market structure. Second, one might attempt to upgrade the supply of minority workers by means of greater investment in education and training. Third, following the labor market segmentation approach, one might recommend solutions lying on the demand side rather than the supply side, with a requirement for government employment and expenditure policy to favor those in the secondary sector. This would include equal opportunity and affirmative action programs.

Critics have suggested changes in both the scope and enforcement of equal opportunity legislation in Canada in order to improve its effectiveness. Instead of the case-by-case approach adopted by most human rights commissions, class action suits, routine investigation of firms,[36] and contract compliance have been advocated.

Equal opportunity legislation may be a necessary condition for the elimination of sexual inequality. But legal approaches are limited because they operate only on the demand side of the problem (that is, the employer side) and do little to change supply (that is, education and training). Moreover, the existing empirical evidence points to only a limited impact of such legislation; the small number of complaints filed is apparently because of ignorance of legislation, lack of resources, and fear of employer reprisals.[37] However, these and other cases do have an educational effect and may have served to enhance public awareness of the need to provide equality of opportunity. ☐

FOOTNOTES

[1] In January 1982, women accounted for more than 40 percent of the Canadian labor force. By the year 2000, the labor force participation rate of women is expected to approach that of men. [9] In this case, the Court struck down educational requirements and employment tests, stating that these requirements could not be justified on the grounds of business necessity because they were not valid or related to job performance, and they had adverse impact because they screened out a greater proportion of blacks than whites. However, if business necessity could be proved, that is, if the educational and testing requirements that had disproportionate or adverse impact on minorities were related to job performance, then the practice was not prohibited.

[36] Apparently, routine investigation of firms does bring increased backpay settlements. For instance, 157 investigations and routine audits under Ontario's equal pay regulations resulted in $284,000 of salary increases and backpay settlements for female employees over a 10-month period, April 1980 to January 1981. Thirty-six employers were found guilty in cases involving 134 women. The beefed-up inspection procedures by the Ministry of Labour were made possible by the hiring of 11 officials who were added to the Ministry's equal pay monitoring team in Spring 1980. See *Globe and Mail,* Feb. 27, 1981, p. B-8. A comparison of previous statistics highlights the role of routine audits in increasing backpay settlements. In 1979–80, nine employers were found guilty involving 44 employees and $56,212 in settlement; in 1978–79, eight employers involving 29 employees were found guilty and the settlement was $8,311; in 1977–78, nine employers involving 20 employees were found guilty and the settlement was $6,672.67. The exception to the rule was during 1976–77 when 29 employers and 452 employees were involved and the settlement was $535,966.02. However, during 1975–76, the settlement sum of $31,248.88 was in line with other years and involved 17 employers and 76 employees. These figures were provided by the Women's Bureau of the Ontario Ministry of Labour.

Major Agreements Expiring Next Month

This list of collective bargaining agreements expiring in November is based on contracts on file in the Bureau's Office of Wages and Industrial Relations. The list includes agreements covering 1,000 workers or more.

Employer and location	Industry	Labor organization[1]	Number of workers
Allis-Chalmers Corp. (La Porte, Ind.)	Machinery	Auto Workers	1,000
Allis-Chalmers Corp. (West Allis, Wis.)	Machinery	Auto Workers	1,900
Apartment Building Owners and Managers Association of Chicago (Illinois)	Services	Service Employees	3,000
Armstrong Cork Co. (Lancaster, Pa.)	Miscellaneous manufacturing	Rubber Workers	2,000
Bendix Autolite Corp. (Michigan)	Transportation equipment	Auto Workers	1,200
Carrier Corp. (Syracuse, N.Y.)	Machinery	Sheet Metal Workers	3,250

Developments in Industrial Relations

Westinghouse workers to contribute to pensions

Only minutes before a July 25 strike deadline, Westinghouse Electric Corp. and three electrical workers' unions agreed on 3-year contracts that included a "contributory" pension plan. In the 1979 negotiations, Westinghouse's demand that workers begin financing part of their pensions resulted in a 7-week strike by the three unions and other union members of the Coordinated Bargaining Committee formed in 1965 to strengthen bargaining with Westinghouse and General Electric Co. Westinghouse maintained that partial financing of pensions by employees was necessary to alleviate a competitive cost advantage held by General Electric, which has had a contributory plan since the early 1950's.

The unions involved were the International Brotherhood of Electrical Workers, the International Union of Electrical, Radio and Machine Workers, and the United Electrical Radio and Machine Workers. All three unions bargain with Westinghouse on a "national" basis for about 31,000 workers. A union official said the decision was not a "concession" and that the unions were not "philosophically opposed" to the concept if Westinghouse made several changes in its proposal. The unions' negotiators also maintained that the Westinghouse contributory plan was better than that at General Electric.

The Westinghouse plan requires employees to contribute an amount equal to 3 percent of annual earnings in excess of $14,700, in contrast to the $12,000 threshold at General Electric. Minimum monthly benefits were increased to a range of $14 to $17.50 a month (depending on preretirement average annual earnings), compared with a range of $12 to $17.50 at General Electric. In 1984, the range will rise to $14 to $19.50 at both companies. The preretirement average annual earnings for Westinghouse retirees will be based on the last 3 years of work, compared with the last 5 years at General Electric. All Westinghouse workers were also given the option of staying in the existing company-financed plan, with the benefit rate remaining at $13 a month.

The pension changes negotiated by the three electrical unions (and subsequently accepted by the other Coordinated Bargaining Committee unions for 9,000 additional workers) were identical to those the Federation of Westinghouse Independent Salaried Unions negotiated in July for 11,000 employees. The Federation had already agreed to a contributory pension plan in its 1979 settlement.

Except for the pension differences, all of the Westinghouse contracts provided for essentially the same wage, benefit, and job security terms as at General Electric (see *Monthly Labor Review*, September 1982, 44–45).

Steel industry update

There were several occurrences in the financially pressed steel industry. The United Steelworkers rejected an employer proposal for labor-cost consessions and efforts to end alleged "dumping" of foreign steel in the United States continued with no clear outcome in sight.

In announcing the rejection of the industry's consession proposals and the termination of negotiations, Steelworkers President Lloyd McBride said the bargainers "have spent a great deal of time trying to find answers to our mutual problems and we simply have failed." He said the talks with the eight Coordinating Committee Steel Companies, which generally set the bargaining pattern for other producers, had floundered because the employers' final proposal "went too far" by indicating "if you can't accept that [the proposals], there's no deal." McBride contended that the proposals called for much greater sacrifices than the revised contracts the Auto Workers negotiated with Ford Motor Co. and General Motors Corp.

The unanimous decision by the union's Basic Steel Industry Conference (which consists of 400 local union officials) drew a bitter response from J. Bruce Johnston, U.S. Steel Corp. vice president and chief industry bargainer. Johnston said that the union's refusal to accept wage and benefit cuts suggests to unemployed steelworkers that their problems will be solved by a recovery in steel order volume, when in fact, it is "their ever-

---

"Developments in Industrial Relations" is prepared by George Ruben of the Division of Developments in Labor-Management Relations, Bureau of Labor Statistics, and is largely based on information from secondary sources.

increasing wage costs [that] are pulling against any sustained recovery for domestic steel."

The rejected proposal would have superseded the remaining year of the current 3-year contract and would have terminated on August 1, 1985. It called for a freeze on wages; suspension of automatic quarterly cost-of-living adjustments; elimination of extended vacations; a 50-cent-an-hour increase in employer financing of Supplemental Unemployment Benefits; guaranteed durations of benefit payments to laid-off workers with 10 years of service; establishment of stock ownership and individual retirement accounts; and a possible contract reopening linked to the level of steel production.

McBride said the parties were not considering a renewal of the Experimental Negotiating Agreement. This opens the possibility of an industry strike if the parties are unable to agree on a new wage-and-benefit contract in 1983. The Experimental Negotiating Agreement, which was introduced in 1973, essentially banned industrywide strikes at the termination of agreements in exchange for an "economic floor" under wage-and benefit settlements.

Meanwhile, Secretary of Commerce Malcolm Baldrige announced that the Reagan Administration would not reopen negotiations with six European nations to gain import limitations. The parties had reached agreement on limits, but the accord was rejected by the seven domestic producers that had filed the unfair trade charges in January against South Africa and Brazil, as well as the European countries. The producers had charged that some nations were unfairly subsidizing steel produced for export to the United States.

Baldrige said a resumption of talks would not be fruitful because "there comes a time when both sides say enough is enough." He maintained that U.S. negotiators had gained all the import restrictions the domestic companies had sought, but the U.S. companies later decided they wanted lower import quotas.

In another aspect of the controversy, the Department of Commerce announced a preliminary finding that the steel products from the six countries were, in fact, being sold in the United States at unfairly low prices. As a result, importers of steel from these nations were required to begin posting bonds to assure payment of penalty duties that could be imposed when the department issues a final ruling later in the year.

Western Union contract ends 90-minute strike

A 90-minute strike against Western Union Telegraph Co. ended when the parent Western Union Corp. and the United Telegraph Workers agreed on a 3-year contract. About 8,800 workers were involved. Later, the Communications Workers agreed to virtually identical terms for the 900 Western Union Telegraph employees it represents in the New York City area.

The United Telegraph Workers accord provided for a reported 31.066-percent increase in wages and benefits over the term, including a 30-percent rise in pension rates. The wage portion of the package calls for increases of 8 percent the first year, 7 percent the second, and 7.1 percent the third. With these increases, pay will average $10.43 an hour, according to the union.

Other terms included additional pay increases for some job classifications, a new optical care plan, and a $50,000 increase in major medical coverage, to $200,000.

Union mergers

A 91,000-member Glass, Pottery, Plastics and Allied Workers union resulted from the merger of the Pottery Workers and the Glass Bottle Blowers unions. Speaking to a special convention of the Pottery Workers, union president James E. Hatfield said the move was necessary to increase "unity and strength" in negotiations with employers. Hatfield will head the new organization, and Pottery Workers' President Lester H. Null will serve as assistant president. The 11,000-member Pottery Workers, which, like the Glass Blowers, traced its origins to the 1800's, had been an autonomous affiliate of the Seafarers from 1976 to 1978.

A 70,000-member Aluminum, Brick and Glass Workers International Union resulted from the merger of the Aluminum, Brick and Clay Workers and the Glass and Ceramic Workers. Aluminum Workers President Lawrence A. Holley will head the new union and will be assisted by Glass and Ceramic Workers President Joseph Roman.

Merger talks between the Steelworkers and the Insurance Workers failed for the second time. The first round of consolidation talks ended in 1980, when the unions were unable to agree on a dues structure. This also was the main barrier to success in the recent talks. The executive board of the Insurance Workers rejected the proposal because of concerns that the formula—1.15 percent of 80 percent of the agents' average earnings—would amount to $20 to $25 a month. Current monthly dues are $11 a month for the Insurance Workers and 2 hours of pay for the Steelworkers.

AFL-CIO Executive Council holds summer session

The summer session of the AFL-CIO Executive Council focused on the economy. In 1 of 16 policy statements, the council charged that Reagan Administration economic actions were pushing "the lowest-paid workers into a frightening abyss of subpoverty" and they are increasingly being joined "by workers with valuable, hard-won skills who previously had a respected place in the community." Further, the council contended, the damage was being exacerbated by "deep budget cuts in social programs at the exact moment the recession makes them so needed."

In a move to strengthen workers' role in the 1984 presidential campaign, the council decided that the Federation's general board (which consists of officials from all the affiliated unions) will meet before the first political primary to decide whether to endorse a candidate. In recent presidential campaigns, the member unions were not unified in their choice and entered the campaign later, which reduced their role in the selection, according to Federation officials. Federation President Lane Kirkland said that member unions will not be bound to back any candidate endorsed by the general board.

In other actions, Kirkland announced formation of committees to examine the changing work force and the organizing outlook; develop and promote greater participation by retirees in attaining labor's objectives; and coordinate efforts to defeat the proposed constitutional amendment requiring a balanced Federal budget.

Maintenance of Way Employees convene

Delegates to the quadrennial convention of the Maintenance of Way Employees approved a plan that could lead either to an autonomous division or a separate union for Canadian members. The 450 delegates, meeting in Vancouver, British Columbia, unanimously endorsed the proposal in a voice vote. The delegates also amended the constitution to provide for the U.S. vice president and executive board members to be elected by delegates from their region, rather than by all U.S. delegates. In other affairs, Ole M. Berge was elected to another term as president of the 120,000 member union, and Geoffrey N. Zeh, the union's general counsel and research director, defeated incumbent B.L. Sorah for the vice presidency.

Electrical workers in New York get raises

About 7,500 workers were covered by a 2-year contract negotiated between the International Brotherhood of Electrical Workers and the Niagara Mohawk Power Co. of Syracuse, N.Y. Wages increased by 9.5 percent on June 1, and will rise an additional 9 percent on June 1, 1983. New employees will be paid $1 an hour less than the current starting rate. Prior to the settlement, pay averaged $11.19 an hour for the 1,900 clerical workers and $11.48 for other workers.

Other terms included a raise in normal pensions, which will be financed by increasing the number of years used in calculating career average annual salary; $300,000 major medical coverage, instead of $200,000; free eye examinations every 2 years for 500 customer service representatives who use video display terminals regularly; changes in work schedules, including one that requires some employees to work as late as 9 p.m. to read the meters of customers who are not home during usual business hours; and a raise (to $20) in the bonus paid to employees who discover a theft of service.

Accord ends 7-week casino strike

Carpenters, painters, and maintenance workers at three hotel-casinos in Atlantic City, N.J., approved a 5-year settlement that was later extended to other hotel-casinos. The accord, which ended a 7-week strike at the Playboy, Bally's Park Place, and Caesar's Boardwalk Regency, called for a 7-percent pay increase in the first year, 8 percent in each of the next 3 years, and 7 percent in the final year. The previous wage rate was $10 an hour for the employees, who are represented by the Operating Engineers, Carpenters, and Painters unions.

The casinos also agreed to pay 25 cents an hour into an annuity fund for the employees during the last 6 months of the contracts. The money will be distributed at retirement, transfer out of the local union, or death.

Wages of Oregon State employees frozen

The State of Oregon, which has been experiencing budget problems because of the economy and, in particular, the severe cutbacks in its lumber and wood products industry, received some aid when State employees agreed to give up $20 million in wages. The Oregon Public Employees Union, which represents half of the workers, agreed to a wage freeze for the fiscal year beginning July 1. The union's 17,000 members had been scheduled for pay increases of 3 percent on July 1 and November 1 of 1982 and March 1, 1983 under their current 2-year contract, negotiated in 1981. In exchange for the freeze, the workers will receive 6 additional paid vacation days during the 12 months.

Instead of a pay freeze, the Teamsters agreed to reduce the paid workweek of State employees it represents to 37.5 hours, from 40.

The pay increases and the 40-hour week will be restored after July 1, 1983. The State also negotiated comparable concessions with 10 other unions.

NLRB orders company to bargain with union

In a departure from usual practice, the National Labor Relations Board ordered a company to bargain with a union even though the union was unable to show support by a majority of the workers. The board said the bargaining order was warranted because the firm, Conair Corp. of Edison, N.J., had engaged in "outrageous and pervasive" conduct to counter an organizing campaign by Local 222 of the Ladies Garment Workers union.

According to the board, the union had obtained authorization cards from 46 percent of the 380 workers early in 1977, but Conair, a maker of hair and beauty care products, had then initiated a massive and unrelenting campaign to defeat the drive. Some of the illegal tactics cited by the board included threats to close the plant and move the operations to Hong Kong and threats that employee benefits would be terminated. Subsequently, the union struck, but was forced to end the walkout after 5 months because of continued coercive tactics by the company. About 9 months after the start of the organizing drive, the union garnered only about one-third of the votes cast in a representation election held in December 1977.

The board held that the order to bargain with Local 222 was necessary because Conair had "foreclosed any possibility of holding a fair representation election," and therefore, "we find that a remedial bargaining order is the only way to restore to employees their statutory right to make a free and uncoerced determination whether they wish to be represented in collective bargaining by a labor organization. Anything short of a bargaining order would deny employees that right which has been the hallmark of national labor policy for nearly five decades."

In the majority opinion, several board members said that Conair's conduct fell within the "exceptional" category specified in the Supreme Court's 1969 decision in Gissel Packing Co. In that ruling, the Court said that when an employer engages in flagrant violations that preclude a fair election, the board could issue a bargaining order "without need of inquiry into majority status on the basis of cards or otherwise."

Serious violations target of mine safety agency

A change in mine safety and health regulations by the Department of Labor indicates it will concentrate on correcting serious violations by mine owners. A spokesman for the Department's Mine Safety and Health Administration said the agency will seek greater penalties for operators who are "found to be negligent" or who do not correct violations, but the agency will now propose only a $20 fine for minor violations. Previously, all penalties were set through a lengthy process based on six criteria. As before, penalties require the approval of the independent Mine Safety and Health Review Commission.

The Bituminous Coal Operators Association applauded the changes, saying that it will reduce paperwork for inspectors and allow everybody to concentrate on the more serious violations. Sam Church, president of the United Mine Workers, said he was disappointed with the reduced penalties for minor violations but noted that the Assistant Secretary of Labor for Mine Safety and Health had promised that the program would not be used by operators to circumvent the law.

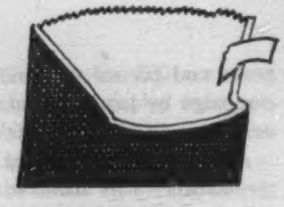
Employer with EEO plan guilty of bias

In a 5 to 4 decision, the Supreme Court held that even an employer with a successful equal employment opportunity program can be guilty of discrimination in administrating parts of the program. The case arose when four black employees of the State of Connecticut's Department of Income Maintenance complained that they failed to gain promotions because the written examination was biased against blacks. In their complaint, filed under provisions of title VII of the Civil Rights Act of 1964, the four employees said that blacks had passed the examination at only 68 percent of the rate for white candidates.

In its response, the State contended that only the overall results of the program should be considered, noting that 23 percent of the blacks who passed the test were promoted, compared with only 13 percent of the whites who passed.

However, the Court rejected the contention. Writing for the majority, Justice William J. Brennan said that the four blacks who failed the test and initiated the complaint did not get promotions, so the fact that other blacks did was not beneficial to the four, that "the principal force of the statute is the protection of the individual employee, rather than the protection of the minority group as a whole." □

Book Reviews



The 'comparable worth' conundrum

Comparable Worth: Issues and Alternatives. Edited by E. Robert Livernash. Washington, Equal Employment Advisory Commission, 1980. 260 pp.

Women, Work, and Wages: Equal Pay for Jobs of Equal Value. Edited by Donald J. Treiman and Heidi I. Hartmann. Washington, National Academy Press, 1981. 136 pp.

If the saying that timing is everything has any validity, then 1982 and its high level of unemployment is probably not an optimum time for action on the pay equity issue of comparable worth. It is, however, a good time to prepare for any future action. To do so, I strongly recommend that people of all persuasions on the issue—for, against, undecided, or unknowledgeable—use the two books in this review as their primers.

Although each has a different outlook, both books agree on two main points. First, that the most generally accepted definition of comparable worth is equal pay for work of comparable (or equal) value; and second, that the comparable worth issue is an extension of the issues covered in the Equal Pay Act of 1963 and Title VII of the Civil Rights Act of 1964.

In simple terms, the Equal Pay Act mandates equal pay for equal work without regard to sex, race, and other factors. It exempts any wage differential attributable to systems of seniority, merit, quantity, or quality of production. Title VII prohibits employment discrimination with respect to pay and terms, conditions, or privileges of employment because of sex, race, and so forth, except when wage differentials are based on systems of seniority, merit, quantity, or quality of production (the Bennett amendment).

After some 15 years of litigation under these laws, many women's groups began to lobby for stronger methods of dealing both with the male-female wage differences that had not sufficiently improved and the seemingly intractable job segregation of women. Thus, in the late 1970's, the comparable worth concept resurfaced, having had a brief tenure during World War II, and earlier periods. (See the excellent historical background provided by Herbert R. Northrup in *Comparable Worth: Issues and Alternatives.*)

Knowing the sponsor of each book provides a good indication of the stand each takes. *Comparable Worth: Issues and Alternatives* was funded by a grant from the Business Roundtable and was published by the private, business-oriented Equal Employment Advisory Council. The book takes an employer-oriented approach and argues strenuously against comparable worth.

Women, Work, and Wages: Equal Pay for Jobs of Equal Value was funded by a grant from the Federal Government's Equal Employment Opportunity Commission and was published by the National Academy of Sciences. This book takes an employee-oriented approach, concluding that sex-based job evaluation and biases still exist and that a comparable worth mechanism should be pursued to remedy the situation.

E. Robert Livernash, Professor Emeritus of the Harvard School of Business, edited the Equal Employment Advisory Council's book. He also wrote the introductory Overview, which is so overwhelmingly subjective and vitriolic, that this is one of the rare times I must recommend reading an Overview last, more as a conclusion. Otherwise, I believe a considerable number of readers, especially women, may be deterred from reading the seven topical chapters, which for the most part, contain a great deal of valuable information.

For example, Janet R. Bellace's excellent chapter on "A Foreign Perspective" discusses the equal pay and comparable worth concept in 13 countries, beginning with ILO Convention 100 in 1951 and Article 19 of the Treaty of Rome in 1957. She points out that today there is hardly any uniformity in defining comparable worth and that in some countries the term is synonymous with equal pay.

In his chapter on "Job Evaluation and Pay Setting," Donald P. Schwab provides a thorough review of the current state of the art, its good points and deficiencies. He emphasizes the importance of external market constraints, such as regulations and unions, in the job evaluation process, as well as the role of internal key and nonkey jobs. Schwab concludes that "At present [1980] there is no mechanism for defensibly establishing comparable worth. Certainly, job evaluation does not do it."

About two-thirds of Herbert R. Northrup's chapter on "Wage Setting and Collective Bargaining" presents exceptionally interesting historical material on wage structure relationships and bargaining techniques between unions and management. The remaining third of the chapter contains a strongly worded case against government intervention and regulation in job evaluation and pay-setting processes. In Northrup's words, "Perhaps the most pernicious aspect of the comparable worth theory is that it would establish a government agency as the final arbiter of wages."

Other chapters and authors are "The Emerging Debate," by George T. Milkovich; "The Market System," by George Hildebrand; "Statistical Biases in the Measurement of Employment Discrimination," by Harry V. Roberts; and "The Legal Framework," by Robert E. Williams and Douglas S. McDowell.

The Equal Employment Advisory Commission volume concludes that comparable worth has neither been operationally defined by its supporters, nor will it ever be, and that a nonarbitrary wage structure requires the use of traditional job evaluation procedures and market rate standards. " . . . any attempted implementation of comparable worth would encounter substantial difficulties and would have disruptive and undesirable consequences." A viable alternative is " . . . the accelerated promotion of women, particularly within the managerial and professional hierarchy," a course which "is being effectively pursued by many companies." Upward mobility programs for workers are seen as the most promising path employers can follow.

The U.S. Equal Employment Opportunity Commission was established in 1965 to enforce Title VII of the Civil Rights Act. In 1977, the EEOC commissioned the National Academy of Sciences to produce a study on the issues involved in obtaining a measure of the comparable worth of jobs. An interim study, *Job Evaluation: An Analytical Review*, was released in 1979. The final volume entitled *Women, Work, and Wages: Equal Pay for Jobs of Equal Value* reflects the work of the 14-member Committee on Occupational Classification and Analysis.

Chair of the committee, Anne R. Miller, Professor of Sociology, University of Pennsylvania, writes in the book's Preface, "The format of the report reflects [the committee's] consensus. A major portion of our early discussion focused on whether, in fact, the existing wage rate is a good approximation of the worth of a job. Our ultimate view, as described in chapter 3 and summarized in chapter 5, is that the substantial influence of institutional and traditional arrangements makes it impossible to view current wage rates as set solely by the free play of neutral forces operating in an entirely open market, no matter how attractive such a theoretical formulation may be. Our examination of the outcomes—that is, the earnings differentials reviewed in chapter 2—and the processes—the arrangements by which workers are allocated and wages are set, covered in chapter 3—led us to that judgment."

Despite the committee's consensus on many important issues, evidence of dissension can be found in the minority and supplementary reports at the end of the book and in some equivocating elsewhere in the book about the feasibility of measuring comparable worth scientifically. One committee member, Ernest McCormick, Professor Emeritus of Industrial Psychology, Purdue University, filed a minority report on two counts. First, he disagreed with the committee about concluding that institutional and traditional arrangements frequently are a major factor in setting current wages. Second, McCormick thought the final report should have included his views on job evaluation procedures.

Another committee member, Gus Tyler, Assistant President, International Ladies' Garment Workers' Union, filed a supplementary report, which was also endorsed by member Mary C. Dunlap, lawyer and lecturer at the University of California, Berkeley. Their statement supports the committee's report but says it is too narrowly focused to have a major impact on the root causes of pay differentials. Tyler and Dunlap believe broader issues are involved, including a maldistribution of workers by sex, with women entering traditionally low paying, service sector jobs; indexing the minimum wage; regulating imports; and supplementing the traditional wage with a social wage (rent supplements, health care, social security, and so forth).

Donald J. Trieman, Professor of Sociology, University of California, and Heidi I. Hartmann, Associate Executive Director, Assembly of Behavioral and Social Sciences, National Academy of Sciences, edited the book's five chapters. Chapter 1 introduces the main points on which the committee focused, with wage discrimination an overwhelming theme. The text states that women who are nurses, librarians, government employees, and clerical workers have assessed their skills and requirements of their jobs and have argued that their jobs are underpaid relative to jobs of comparable worth that are held by men—that is, jobs requiring similar levels of skill, effort, and responsibility and similar working conditions. " . . . the issue raised is that of pay equity in a labor market that is highly segregated by sex. While the opportunity to move out of segregated job categories may be welcome to many women, many others, who have invested considerable time in training for their jobs, demand wage adjustments in 'women's jobs' rather than opportunities to work in other jobs."

Taken together, chapters 2, 3, and 4 present a superb roundup of statistics and research, including reviews of many studies of sex differences in earnings, empirical and theoretical frameworks for investigating earnings inequalities, and the efficacy of various econometric modeling techniques in determining wage discrimination.

Chapter 2, "Evidence Regarding Wage Differentials," takes the reader through a thicket of statistics, studies, and theories in an effort to pinpoint the underlying reasons for earnings inequalities by sex. Provided are exceptionally clear discussions about the explanatory value of human capital factors and about measures of segregation within occupations and firms.

This chapter concludes that because wages may not reflect the entire reward paid for a job and that differences in the productivity of many workers are neither easily nor accurately measured, measures of wage discrimination often cannot be obtained with a high degree of confidence.

Chapter 3, "Wage Differentials and Institutional Features of Labor Markets," emphasizes the belief of institutional economics that while wage rates reflect the forces of supply and demand, supply and demand themselves are strongly affected by such institutional factors as union contracts, promotions from within firms, and segmentation of workers into noncompeting groups on the basis of sex, race, and so forth.

This chapter's discussion on job segregation is especially provocative, including the historical information on women's underpayment in the labor markets of the 1930's and World War II.

Chapter 4, "Wage Adjustment Approaches to Overcoming Discrimination," reviews a variety of job evaluation procedures that adjust wages through conventional factor point methods and statistical adjustments of pay rates to estimate and remove the effects of the sex, race, and ethnic composition of job categories. The committee concludes that, "Techniques used in job evaluation have not kept pace with developments in econometrics, psychometrics, and sociological measurement. Serious attention should be given to the selection and measurement of compensable factors, the functional form of regression models, and assumptions about error structures, each of which can seriously affect the factor weights and the pay rates predicted by these models."

The conclusion of the National Academy of Sciences book (chapter 5) seems a bit schizophrenic; that is, the committee's review of the evidence "strongly suggests that wage discrimination is widespread." But "would the low-paying jobs be low-paying regardless of who held them, or are they low-paying jobs because of the sex, race, or ethnic composition of their incumbents?" In the committee's judgment, a correct response recognizes that both elements account for observed earnings differentials.

I have not dwelled on the few misprints and errors in some of the tables and text in both volumes. Readers will discover these on their own. I believe, however, that they do not detract from the richness of the information and opinions provided. We are indeed fortunate to have available two highly readable books with different views on such a controversial subject.

Retirement issues: required reading

The Economics of Aging: The Future of Retirement. Edited by Malcolm H. Morrison. New York, Van Nostrand Reinhold Co., 1982. 294 pp. $24.

This book focuses upon several key issues pertaining to our national retirement policies and programs. It especially emphasizes the areas of social security, other public and private retirement income programs, and employment policies and programs for older workers. All seven chapters are clearly written but some are a little redundant. Several chapters contain both analytical and new material on the subjects covered. I believe that *Economics of Aging* will become a major reference for those working in the broad fields of aging, income maintenance, and employment.

The introductory chapter by Ruth Blank is a comprehensive discussion of the history of retirement as a social institution in preindustrial, industrial, and postindustrial America. It has a most complete set of references on retirement practices and programs in the United States.

The second chapter, by Elizabeth Meier and Barbara Boyle Torrey, is a scholarly discussion of future demographic changes and retirement age policy in the United States. This includes an interesting discussion of the likely consequences of an increasing dependency ratio that will see, in the next century, a smaller working population having to transfer more of its income to a larger retired population, especially after the year 2010. Meier and Torrey argue that some increase in the normal retirement age (65) seems economically and socially desirable. However, they do caution that any increase in the eligibility age for retirement benefits in social security and other public and private retirement income programs should be planned thoughtfully and introduced gradually over a number of years.

The next two chapters are major contributions to the social policy literature on retirement income issues. Chapter 3, by Eric Kingson, is an excellent discussion of current retirement trends, including both voluntary and involuntary early retirement trends, barriers to the continued employment of older workers, and an assessment of both the voluntary and involuntary factors that govern why people leave the work force prior to age 65. The section on early retirement trends should be required reading for any one who wishes to participate in the current and future debate regarding changing the retirement age in the massive social security program. Kingson, whose major academic research is the area of early retirement practices and trends, cautions against raising the normal social security age past 65. He believes, and I agree, that such a move could greatly acerbate the economic position of involuntary early retirees, by, in effect, forcing them to retire on greatly actuarially reduced benefits than is now the case in social security and various public and private retirement income programs.

Chapter 4, by Gary Hendrick and James Storey of the Urban Institute, is a broad and incisive analysis of the characteristics and goals of social security, public employee retirement plans, private pensions, and tax subsidies. Hendrick's and Storey's major retirement policy questions: When should nondisabled workers retire? How should various retirement benefits be coordinated? What proportion of workers' former earnings should be replaced by retirement? When should nondisabled workers retire? How should retirement benefits be adjusted for inflation or economic growth, and so on. I was impressed by the authors' candor in addressing these and other questions in their discussion. The chapter includes a section on specific policy responses to these questions. Their agenda would include, in part, a gradual rise in the retirement age in social security, improving benefits to a 70- to 75-percent wage replacement level for workers at or below the median wage, modifying the present "indexing" system of benefits, and eliminating the so-called "welfare" aspects of social security. It is not a tame agenda by any standard.

The final three chapters concentrate on employment policies and programs for older persons. Chapter 5, by Charles Harris and Dorothy Bauer, discusses current employment programs and current and projected employment prospects for older workers. They foresee a somewhat optimistic future for the next generation of older workers—a debatable point. Their review of current programs is inclusive but largely descriptive. I would have appreciated a much stronger analysis and critique of the role, or nonrole, of the U.S. Employment Service in aiding older workers. They do point out, however, that over the years there has been strong resistance in the field of manpower and employment in serving the older worker population.

Chapter 6, covering the subject of age discrimination and mandatory retirement, by Edward Howard, Nancy Peavy, and Lauren Selden, is a superior piece of policy analysis and scholarship. They discuss, in depth, the evolution and implementation of the Age Discrimination in Employment Act of 1967 and 1978. Their section on the issues and problems that have been associated with the enforcement of this act is excellent. I also liked their description of the dynamics of the legislative process associated with the 1978 law.

The book concludes with an interesting discussion by Malcolm Morrison on the need for a broader range of alternative work patterns and more flexible retirement options and a brief summary. Morrison is disturbed over, and raises several objections to, the prevalent "linear life pattern" of education, work, and retirement in our society. He believes such a pattern is dysfunctional and contributes to various employment problems of both younger and older workers. He suggests and recommends that a number of employment and retirement options be introduced into the work force. These would include reduced workweek schedules prior to retirement; extra vacation time in the years prior to retirement, reduced hours of work, job transfer programs, and other innovations being experimented with currently in the Scandinavian countries, West Germany, and France.

Book notes

Youth Without Work, Three Countries Approach the Problem. By Shirley Williams and others. Paris, France, Organization for Economic Cooperation and Development, 1981. 255 pp. $15, OECD Publications and Information Center, Washington, D.C. 20006.

Employment among young people in many countries is hindered by traditional and rigid institutional attitudes such as antipathy towards hiring young people, especially minorities; refusal to train young women in nontraditional occupations; and reluctance to allow vocational training in school.

This book analyzes the youth employment problem of three countries in the Organization for Economic Cooperation and Development (OECD): Denmark, West Germany, and the United States. It also analyzes their educational and training policies and provides recommendations.

In Denmark, unemployment among persons 18 to 25 years of age was much higher than for those under 18 years of age. A high guaranteed minimum wage for workers 18 years of age and over and highly regulated collective agreements between employers and unions have affected youth employment and added to labor market segmentation.

Of all OECD countries, the Federal Republic of Germany has the most elaborate transition system from school to work. The author maintains, however, that West Germany underestimates the unemployment measurement of their youngsters by including them in the labor force figure (denominator) and excluding them from the unemployed figure (numerator) if they are seeking an apprenticeship.

The United States created 12 million jobs in the public and private sectors during the 1970's, but an increased number of middle-aged women returned to the labor force and filled over 7 million jobs. Unemployment among young people remained high. The authors advocate expansion of apprenticeships and other training programs to enlarge the supply of skilled labor.

Company Productivity: Measurement for Improvement. By Irving H. Siegel. Kalamazoo, Mich., W. E. Upjohn Institute for Employment Research, 1980. 88 pp. $3.50, paper.

American businessmen have become more concerned with improvement of national productivity performance, which is generally recognized as essential for countering inflation and preserving jobs and living standards.

Irving H. Siegel maintains that companies can inexpensively improve their productivity performance by adoption and use of a system for measuring it. He offers a practical application of measurement techniques and notes a number of specific ways in which a system can improve organizational performance. Siegel points out that productivity monitoring may help a company anticipate and locate operational anomalies and take corrective steps and appraise the effectiveness of such remedial action.

Working-Class Life "The American Standard" in Comparative Perspective, 1899–1913. By Peter R. Shergold. Pittsburgh, University of Pittsburgh Press, 1982. 306 pp. $21.95.

In his provocative work, Peter R. Shergold compiles extensive data on the standards of living in Pittsburgh and Birmingham in the first decade of the century. Mining the Pittsburgh Survey, various bulletins and reports of the U.S. Bureau of Labor, reports of the British Board of Trade, and many other sources, Shergold develops substantial materials on wages, hours, diet, food prices, rents, fuel, and clothing costs, as well as labor force participation by women and children. His announced goal is to examine the thesis that high wages gave the American worker a high standard of living, thus encouraging a conservative "business" unionism rather than a revolutionary labor movement. Indeed, Shergold finds that the skilled worker in Pittsburgh did earn higher wages than his counterpart in Birmingham. At the same time, however, the unskilled earned about the same, and, in fact, the Birmingham laborer enjoyed more leisure time and greater security against unemployment.

Shergold acknowledges the influence on his work of Alan Dawley, David Brody, and Herbert Gutman, radical American labor historians. Ironically, his findings seem to contradict their working-class ideology. Indeed, Shergold emphasizes the wide range of wage rates found in Pittsburgh, a structure reinforced by ethnic and racial prejudice: "American workers found it profoundly difficult to perceive their very diverse lifestyles as the product of a common exploitation."

The book leaves many questions unanswered. Indeed, the author poses a number of topics for further study. And, he seems at times overwhelmed by the discussion of methodology. Yet, Shergold shows the value to labor history of detailed economic analysis, and one might wish for more such investigation rather than the ideological debates frequently encountered in the field.

Steelmasters and Labor Reform, 1886–1923. By Gerald G. Eggert. Pittsburgh, University of Pittsburgh Press, 1981. 212 pp. $17.95.

Formation of the U.S. Steel Corporation in 1901 symbolized the technological, managerial, and financial revolutions reshaping American economic institutions, and William Brown Dickson's career spanned crucial, formative years. Beginning in 1881 as a manual laborer at Carnegie's Homestead mill, Dickson left the Steel Corporation in 1911, resigning his position as first vice president. As an officer in the corporation, he had fought for two major reforms: safety programs and shorter hours. He carried his ideas into Midvale Steel and Ordnance, which he helped form in 1915 and which he served as vice president and treasurer until its demise in 1923, establishing an employee representation plan during World War I.

Dickson's high position and reform interests put him at the heart of the Steel Corporation's deliberations, and Gerald G. Eggert provides an insider's view of the struggles for power and control within the corporation, the establishment of labor policy, and the birth of "welfare capitalism." Indeed, Dickson's difficulties at U.S. Steel and Midvale emphasized the inherent limitations of the "welfare" or "industrial betterment" movement.

It is a useful story but rather limited. Eggert sets the context well in the introduction, but he relies on Dickson's papers, Steel Corporation minutes, and *Iron Age* for the bulk of his sources, and he focuses on Dickson. The result is a book longer on anecdote than on interpretation and analysis of broader implications.

Notes on Current Labor Statistics 58

Schedule of release dates for major BLS statistical series 58

Employment data from household survey. Definitions and notes 59
- 1. Employment status of noninstitutional population, selected years, 1950–81 59
- 2. Employment status by sex, age, and race, seasonally adjusted 60
- 3. Selected employment indicators, seasonally adjusted 61
- 4. Selected unemployment indicators, seasonally adjusted 62
- 5. Unemployment rates, by sex and age, seasonally adjusted 63
- 6. Unemployed persons, by reason for unemployment, seasonally adjusted 63
- 7. Duration of unemployment, seasonally adjusted 63

Employment, hours, and earnings data from establishment surveys. Definitions and notes . 64
- 8. Employment by industry, selected years, 1950–81 65
- 9. Employment by State 65
- 10. Employment by industry division and major manufacturing group, seasonally adjusted 66
- 11. Hours and earnings, by industry division, selected years, 1950–81 67
- 12. Weekly hours, by industry division and major manufacturing group, seasonally adjusted 68
- 13. Hourly earnings, by industry division and major manufacturing group 69
- 14. Hourly Earnings Index, by industry division 69
- 15. Weekly earnings, by industry division and major manufacturing group 70

Unemployment insurance data. Definitions 71
- 16. Unemployment insurance and employment service operations 71

Price data. Definitions and notes 72
- 17. Consumer Price Index, 1967–81 73
- 18. Consumer Price Index, U.S. city average, general summary and selected items 73
- 19. Consumer Price Index, cross-classification of region and population size class 79
- 20. Consumer Price Index, selected areas 80
- 21. Producer Price Indexes, by stage of processing 81
- 22. Producer Price Indexes, by commodity groupings 82
- 23. Producer Price Indexes, for special commodity groupings 84
- 24. Producer Price Indexes, by durability of product 84
- 25. Producer Price Indexes for the output of selected SIC industries 84

Productivity data. Definitions and notes 87
- 26. Annual indexes of productivity, hourly compensation, unit costs, and prices, selected years, 1950–81 87
- 27. Annual changes in productivity, hourly compensation, unit costs, and prices, 1971–81 88
- 28. Quarterly indexes of productivity, hourly compensation, unit costs, and prices, seasonally adjusted 88
- 29. Percent change from preceding quarter and year in productivity, hourly compensation, unit costs, and prices . . 89

Wage and compensation data. Definitions 90
- 30. Employment Cost Index 91
- 31. Employment Cost Index, wages and salaries, by occupation and industry group 92
- 32. Employment Cost Index, private nonfarm workers, by bargaining status, region, and area size 93
- 33. Wage and compensation change, major collective bargaining settlements, 1977 to date 94
- 34. Effective wage adjustments in collective bargaining units covering 1,000 workers or more, 1977 to date 94

Work stoppage data. Definition 95
- 35. Work stoppages involving 1,000 workers or more, 1947 to date 95

NOTES ON CURRENT LABOR STATISTICS

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics. A brief introduction to each group of tables provides definitions, notes on the data, sources, and other material usually found in footnotes.

Readers who need additional information are invited to consult the BLS regional offices listed on the inside front cover of this issue of the *Review*. Some general notes applicable to several series are given below.

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might otherwise mask short-term movements of the statistical series. Tables containing these data are identified as "seasonally adjusted." Seasonal effects are estimated on the basis of past experience. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years.

Seasonally adjusted labor force data in tables 2–7 were revised in the March 1982 issue of the *Review* to reflect experience through 1981. The original estimates also were revised to 1970 to reflect 1980 census population controls.

Beginning in January 1980, the BLS introduced two major modifications in the seasonal adjustment methodology for labor force data. First, the data are being seasonally adjusted with a new procedure called X-11/ARIMA, which was developed at Statistics Canada as an extension of the standard X-11 method. A detailed description of the procedure appears in *The X-11 ARIMA Seasonal Adjustment Method* by Estela Bee Dagum (Statistics Canada Catalogue No. 12-564E, February 1980). The second change is that seasonal factors are now being calculated for use during the first 6 months of the year, rather than for the entire year, and then are calculated at mid-year for the July-December period. Revisions of historical data continue to be made only at the end of each calendar year.

Annual revision of the seasonally adjusted payroll data shown in tables 10, 12, and 14 were made in August 1981 using the X-11 ARIMA seasonal adjustment methodology. New seasonal factors for productivity data in tables 28 and 29 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month to month and from quarter to quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of $3 and a current price index number of 150, where 1967 = 100, the hourly rate expressed in 1967 dollars is $2 ($3/150 × 100 = $2). The resulting values are described as "real," "constant," or "1967" dollars.

Availability of information. Data that supplement the tables in this section are published by the Bureau of Labor Statistics in a variety of sources. Press releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule given below. The *BLS Handbook of Labor Statistics*, Bulletin 2070, provides more detailed data and greater historical coverage for most of the statistical series presented in the *Monthly Labor Review*. More information from the household and establishment surveys is provided in *Employment and Earnings*, a monthly publication of the Bureau. Historically, comparable information from the establishment survey is published in two comprehensive data books—*Employment and Earnings, United States* and *Employment and Earnings, States and Areas*, and their annual supplements. More detailed information on wages and other aspects of collective bargaining appears in the monthly periodical, *Current Wage Developments*. More detailed price information is published each month in the periodicals, the *CPI Detailed Report* and *Producer Prices and Price Indexes*.

Symbols

p = preliminary. To improve the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.
r = revised. Generally, this revision reflects the availability of later data but may also reflect other adjustments.
n.e.c. = not elsewhere classified.

Schedule of release dates for major BLS statistical series

Series	Release date	Period covered	Release date	Period covered	MLR table number
Employment situation	October 8	September	November 5	October	1–10
Producer Price Index	October 15	September	November 16	October	21–25
Consumer Price Index	October 26	September	November 23	October	17–20
Real earnings	October 26	September	November 23	October	11–15
Major collective bargaining settlements	October 27	1st 9 months	....	....	33–34
Productivity and costs:					
Nonfarm business and manufacturing	October 28	3rd quarter	....	....	26–29
Nonfinancial corporations	....	....	November 29	3rd quarter	26–29

EMPLOYMENT DATA FROM THE HOUSEHOLD SURVEY

EMPLOYMENT DATA in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 60,000 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons are (1) those who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work because they were on layoff or waiting to start new jobs within the next 30 days are also counted among the unemployed. The **unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **civilian labor force** consists of all employed or unemployed persons in the civilian noninstitutional population; the **total labor force** includes military personnel. Persons **not in the labor force** are those not classified as employed or unemployed; this group includes persons retired, those engaged in their own housework, those not working while attending school, those unable to work because of long-term illness, those discouraged from seeking work because of personal or job market factors, and those who are voluntarily idle. The **noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy.

Full-time workers are those employed at least 35 hours a week; **part-time workers** are those who work fewer hours. Workers on part-time schedules for economic reasons (such as slack work, terminating or starting a job during the week, material shortages, or inability to find full-time work) are among those counted as being on full-time status, under the assumption that they would be working full time if conditions permitted. The survey classifies unemployed persons in full-time or part-time status by their reported preferences for full-time or part-time work.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the preceding years. These adjustments affect the comparability of historical data presented in table 1. A description of these adjustments and their effect on the various data series appear in the Explanatory Notes of *Employment and Earnings*.

Data in tables 2–7 are seasonally adjusted, based on the seasonal experience through December 1981.

1. Employment status of the noninstitutional population, 16 years and over, selected years, 1950–81

[Numbers in thousands]

---

[1] The population and Armed Forces figures are not seasonally adjusted.

[2] Civilian employment as a percent of the total noninstitutional population (including Armed Forces).

NOTE: Detail for the above race and Hispanic-origin groups will not sum to totals because data for the "other races" group are not presented and Hispanics are included in both the white and black population groups.

3. Selected employment indicators, seasonally adjusted

EMPLOYMENT, HOURS, AND EARNINGS DATA FROM ESTABLISHMENT SURVEYS

EMPLOYMENT, HOURS, AND EARNINGS DATA in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by 177,000 establishments representing all industries except agriculture. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

Definitions

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in manufacturing include blue-collar worker supervisors and all nonsupervisory workers closely associated with production operations. Those workers mentioned in tables 11–15 include production workers in manufacturing and mining; construction workers in construction; and nonsupervisory workers in transportation and public utilities; in wholesale and retail trade; in finance, insurance, and real estate; and in services industries. These groups account for about four-fifths of the total employment on private nonagricultural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W). The **Hourly Earnings Index** is calculated from average hourly earnings data adjusted to exclude the effects of two types of changes that are unrelated to underlying wage-rate developments: fluctuations in overtime premiums in manufacturing (the only sector for which overtime data are available) and the effects of changes and seasonal factors in the proportion of workers in high-wage and low-wage industries.

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received and are different from standard or scheduled hours. **Overtime hours** represent the portion of gross average weekly hours which were in excess of regular hours and for which overtime premiums were paid.

Notes on the data

Establishment data collected by the Bureau of Labor Statistics are periodically adjusted to comprehensive counts of employment (called "benchmarks"). The latest complete adjustment was made with the release of May 1982 data, published in the July 1982 issue of the *Review*. Consequently, data published in the *Review* prior to that issue are not necessarily comparable to current data. Complete comparable historical unadjusted and seasonally adjusted data are published in a Supplement to Employment and Earnings (unadjusted data from April 1977 through February 1982 and seasonally adjusted data from January 1974 through February 1982) and in *Employment and Earnings, United States, 1909–78*, BLS Bulletin 1312–11 (for prior periods).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20. See also *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976).

NOTE: The industry divisions of mining; construction; tobacco manufactures (a major manufacturing group, nondurable goods); transportation and public utilities; and finance, insurance, and real estate are no longer shown. This is because the seasonal component in these is small relative to the trend-cycle, or irregular components, or both, and consequently cannot be precisely separated.

UNEMPLOYMENT INSURANCE DATA

NATIONAL UNEMPLOYMENT INSURANCE DATA are compiled monthly by the Employment and Training Administration of the U.S. Department of Labor from monthly reports of unemployment insurance activity prepared by State agencies. Railroad unemployment insurance data are prepared by the U.S. Railroad Retirement Board.

Definitions

Data for **all programs** represent an unduplicated count of insured unemployment under State programs, Unemployment Compensation for Ex-Servicemen, and Unemployment Compensation for Federal Employees, and the Railroad Insurance Act.

Under both State and Federal unemployment insurance programs for civilian employees, insured workers must report the completion of at least 1 week of unemployment before they are defined as unemployed. Persons not covered by unemployment insurance (about 10 percent of the labor force) and those who have exhausted or not yet earned benefit rights are excluded from the scope of the survey. **Initial claims** are notices filed by persons in unemployment insurance programs to indicate they are out of work and wish to begin receiving compensation. A claimant who continued to be unemployed a full week is then counted in the insured unemployment figure. The **rate of insured unemployment** expresses the number of insured unemployed as a percent of the average insured employment in a 12-month period.

An **application** for benefits is filed by a railroad worker at the beginning of his first period of unemployment in a benefit year; no application is required for subsequent periods in the same year. **Number of payments** are payments made in 14-day registration periods. The **average amount of benefit payment** is an average for all compensable periods, not adjusted for recovery of overpayments or settlement of underpayments. However, **total benefits** paid have been adjusted.

16. Unemployment insurance and employment service operations

[1] Initial claims and State insured unemployment include data under the program for Puerto Rican sugarcane workers.

[2] Excludes transition claims under State programs.

[3] Excludes data on claims and payments made jointly with other programs.

[4] Excludes data on claims and paumments made jointly with State programs.

[5] Cumulative total for fiscal year (October 1-September 30). Data computed quarterly.

NOTE: Data for Puerto Rico and the Virgin Islands included. Dashes indicate data not available.

r=revised.

p=preliminary.

PRICE DATA

PRICE DATA are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period (1967 = 100, unless otherwise noted).

Definitions

The **Consumer Price Index** is a monthly statistical measure of the average change in prices in a fixed market basket of goods and services. Effective with the January 1978 index, the Bureau of Labor Statistics began publishing CPI's for two groups of the population. One index, a new CPI for All Urban Consumers, covers 80 percent of the total noninstitutional population; and the other index, a revised CPI for Urban Wage Earners and Clerical Workers, covers about half the new index population. The All Urban Consumers index includes, in addition to wage earners and clerical workers, professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctor's and dentist's fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items is kept essentially unchanged between major revisions so that only price changes will be measured. Prices are collected from over 18,000 tenants, 24,000 retail establishments, and 18,000 housing units for property taxes in 85 urban areas across the country. All taxes directly associated with the purchase and use of items are included in the index. Because the CPI's are based on the expenditures of two population groups in 1972–73, they may not accurately reflect the experience of individual families and single persons with different buying habits.

Though the CPI is often called the "Cost-of-Living Index," it measures only price change, which is just one of several important factors affecting living costs. Area indexes do not measure differences in the level of prices among cities. They only measure the average change in prices for each area since the base period.

Producer Price Indexes measure average changes in prices received in primary markets of the United States by producers of commodities in all stages of processing. The sample used for calculating these indexes contains about 2,800 commodities and about 10,000 quotations per month selected to represent the movement of prices of all commodities produced in the manufacturing, agriculture, forestry, fishing, mining, gas and electricity, and public utilities sectors. The universe includes all commodities produced or imported for sale in commercial transactions in primary markets in the United States.

Producer Price Indexes can be organized by stage of processing or by commodity. The stage of processing structure organizes products by degree of fabrication (that is, finished goods, intermediate or semifinished goods, and crude materials). The commodity structure organizes products by similarity of end-use or material composition.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States, from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

In calculating Producer Price Indexes, price changes for the various commodities are averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1972. The detailed data are aggregated to obtain indexes for stage of processing groupings, commodity groupings, durability of product groupings, and a number of special composite groupings.

Price indexes for the output of selected SIC industries measure average price changes in commodities produced by particular industries, as defined in the *Standard Industrial Classification Manual 1972* (Washington, U.S. Office of Management and Budget, 1972). These indexes are derived from several price series, combined to match the economic activity of the specified industry and weighted by the value of shipments in the industry. They use data from comprehensive industrial censuses conducted by the U.S. Bureau of the Census and the U.S. Department of Agriculture.

Notes on the data

Beginning with the May 1978 issue of the *Review*, regional CPI's cross classified by population size, were introduced. These indexes will enable users in local areas for which an index is not published to get a better approximation of the CPI for their area by using the appropriate population size class measure for their region. The cross-classified indexes will be published bimonthly. (See table 19.)

For further details about the new and the revised indexes and a comparison of various aspects of these indexes with the old unrevised CPI, see *Facts About the Revised Consumer Price Index*, a pamphlet in the Consumer Price Index Revision 1978 series. See also *The Consumer Price Index: Concepts and Content Over the Years*, Report 517, revised edition (Bureau of Labor Statistics, May 1978).

For interarea comparisons of living costs at three hypothetical standards of living, see the family budget data published in the *Handbook of Labor Statistics, 1977*, Bulletin 1966 (Bureau of Labor Statistics, 1977), tables 122–133. Additional data and analysis on price changes are provided in the *CPI Detailed Report* and *Producer Prices and Price Indexes*, both monthly publications of the Bureau.

As of January 1976, the Wholesale Price Index (as it was then called) incorporated a revised weighting structure reflecting 1972 values of shipments. From January 1967 through December 1975, 1963 values of shipments were used as weights.

For a discussion of the general method of computing consumer, producer, and industry price indexes, see *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976), chapters 13–15. See also John F. Early, "Improving the measurement of producer price change," *Monthly Labor Review*, April 1978, pp. 7–15. For industry prices, see also Bennett R. Moss, "Industry and Sector Price Indexes," *Monthly Labor Review*, August 1965, pp. 974–82.

---

[1] Data for April 1982 have been revised to reflect the availability of late reports and corrections by respondents. All data are subject to revision 4 months after original publication.

[2] Prices for natural gas are lagged 1 month.

[3] Includes only domestic production.

[4] Most prices for refined petroleum products are lagged 1 month.

[5] Some prices for industrial chemicals are lagged 1 month.

r=revised.

23. Producer Price Indexes, for special commodity groupings

[1967 = 100 unless otherwise specified]

Commodity grouping	Annual average 1981	1981					1982							
		Aug.	Sept.	Oct.	Nov.	Dec.	Jan.	Feb.	Mar.	Apr.[1]	May	June	July	Aug.
All commodities — less farm products	295.7	298.7	299.5	299.5	299.4	300.0	302.0	301.9	301.4	300.9	301.1	302.3	304.1	304.3

[1] Data for April 1982 have been revised to reflect the availability of late reports and corrections by respondents. All data are subject to revision 4 months after original publication.

[2] Not available.

r = revised.

PRODUCTIVITY DATA

PRODUCTIVITY DATA are compiled by the Bureau of Labor Statistics from establishment data and from estimates of compensation and output supplied by the U.S. Department of Commerce and the Federal Reserve Board.

Definitions

Output is the constant dollar gross domestic product produced in a given period. Indexes of **output per hour of labor input**, or labor productivity, measure the value of goods and services produced per hour of labor. **Compensation per hour** includes wages and salaries of employees plus employers' contributions for social insurance and private benefit plans. The data also include an estimate of wages, salaries, and supplementary payments for the self-employed, except for nonfinancial corporations, in which there are no self-employed. **Real compensation per hour** is compensation per hour adjusted by the Consumer Price Index for All Urban Consumers.

Unit labor cost measures the labor compensation cost required to produce one unit of output and is derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from the current dollar gross domestic product and dividing by output. In these tables, **unit nonlabor costs** contain all the components of unit nonlabor payments except unit profits. **Unit profits** include corporate profits and inventory valuation adjustments per unit of output.

The **implicit price deflator** is derived by dividing the current dollar estimate of gross product by the constant dollar estimate, making the deflator, in effect, a price index for gross product of the sector reported.

The use of the term "man hours" to identify the labor component of productivity and costs, in tables 26 through 29, has been discontinued. **Hours of all persons** is now used to describe the labor input of payroll workers, self-employed persons, and unpaid family workers. **Output per all-employee hour** is now used to describe labor productivity in nonfinancial corporations where there are no self-employed.

Notes on the data

In the business sector and the nonfarm business sector, the basis for the output measure employed in the computation of output per hour is Gross Domestic Product rather than Gross National Product. Computation of hours includes estimates of nonfarm and farm proprietor hours.

Output data are supplied by the Bureau of Economic Analysis, U.S. Department of Commerce, and the Federal Reserve Board. Quarterly manufacturing output indexes are adjusted by the Bureau of Labor Statistics to annual estimates of output (gross product originating) from the Bureau of Economic Analysis. Compensation and hours data are from the Bureau of Economic Analysis and the Bureau of Labor Statistics.

Beginning with the September 1982 issue of the *Review*, all of the productivity and cost measures contained in these tables are based on revised output and compensation measures released by the Bureau of Economic Analysis in July as part of the regular revision cycle of the National Income and Product Accounts. Measures of labor input have been revised to reflect results of the 1980 census, and seasonal factors have been recomputed for use in the preparation of quarterly measures. The word "private" is no longer being used as part of the series title of one of the two business sector measures prepared by BLS; no change has been made in the definition or content of the measures as a result of this change.

26. Annual indexes of productivity, hourly compensation, unit costs, and prices, selected years, 1950–81

WAGE AND COMPENSATION DATA

DATA FOR THE EMPLOYMENT COST INDEX are reported to the Bureau of Labor Statistics by a sample of 2,000 private nonfarm establishments and 750 State and local government units selected to represent total employment in those sectors. On average, each reporting unit provides wage and compensation information on five well-specified occupations.

Data on negotiated wage and benefit changes are obtained from contracts on file at the Bureau, direct contact with the parties, and secondary sources.

Definitions

The **Employment Cost Index** (ECI) is a quarterly measure of the average change in the cost of employing labor. The rate of total compensation, which comprises wages, salaries, and employer costs for employee benefits, is collected for workers performing specified tasks. Employment in each occupation is held constant over time for all series produced in the ECI, except those by region, bargaining status, and area. As a consequence, only changes in compensation are measured. Industry and occupational employment data from the 1970 Census of Population are used in deriving constant weights for the ECI. While holding total industry and occupational employment fixed, in the estimation of indexes by region, bargaining status, and area, the employment in those measures is allowed to vary over time in accord with changes in the sample. The rate of change (in percent) is available for wages and salaries, as well as for total compensation. Data are collected for the pay period including the 12th day of the survey months of March, June, September, and December. The statistics are neither annualized nor adjusted for seasonal influence.

Wages and salaries consist of earnings before payroll deductions, excluding premium pay for overtime, work on weekends and holidays, and shift differentials. Production bonuses, incentive earnings, commissions, and cost-of-living adjustments are included; nonproduction bonuses are included with other supplemental pay items in the benefits category; and payments-in-kind, free room and board, and tips are excluded. *Benefits* include supplemental pay, insurance, retirement and savings plans, and hours-related and legally required benefits.

Data on negotiated wage changes apply to private nonfarm industry collective bargaining agreements covering 1,000 workers or more. Data on compensation changes apply only to those agreements covering 5,000 workers or more. *First-year* wage or compensation changes refer to average negotiated changes for workers covered by settlements reached in the period and implemented within the first 12 months after the effective date of the agreement. *Changes over the life of the agreement* refer to all adjustments specified in the contract, expressed as an average annual rate. These measures exclude wage changes that may occur under cost-of-living adjustment clauses, that are triggered by movements in the Consumer Price Index. *Wage-rate changes* are expressed as a percent of straight-time hourly earnings; *compensation changes* are expressed as a percent of total wages and benefits.

Effective wage adjustments reflect all negotiated changes implemented in the reference period, regardless of the settlement date. They include changes from settlements reached during the period, changes deferred from contracts negotiated in an earlier period, and cost-of-living adjustments. The data also reflect contracts providing for no wage adjustment in the period. Effective adjustments and each of their components are prorated over all workers in bargaining units with at least 1,000 workers.

Notes on the data

The Employment Cost Index data series began in the fourth quarter of 1975, with the quarterly percent change in wages and salaries in the private nonfarm sector. Data on employer costs for employee benefits were included in 1980, to produce a measure of the percent change in employers' cost for employees' total compensation. State and local government units were added to the ECI coverage in 1981, providing a measure of total compensation change in the civilian nonfarm economy.

Data for the broad white-collar, blue-collar, and service worker groups, and the manufacturing, nonmanufacturing, and service industry groups are presented in the ECI. Additional occupation and industry detail are provided for the wages and salaries component of total compensation in the private nonfarm sector. For State and local government units, additional industry detail is shown for both total compensation and its wages and salaries component.

Historical indexes (June 1981 = 100) of the quarterly rates of changes presented in the ECI are also available.

For a more detailed discussion of the ECI, see chapter 25, "The Employment Cost Index," of the BLS *Handbook of Methods* (Bulletin 1910), and the *Monthly Labor Review* articles: "Employment Cost Index: a measure of change in the 'price of labor,'" July 1975; "How benefits will be incorporated into the Employment Cost Index," January 1978; and "The Employment Cost Index: recent trends and expansion," May 1982.

Additional data for the ECI and other measures of wage and compensation changes appear in *Current Wage Developments*, a monthly periodical of the Bureau.

34. Effective wage adjustments in collective bargaining units covering 1,000 workers or more, 1977 to date

Measure	Year					Year and quarter								
						1980			1981				1982 p	
	1977	1978	1979	1980	1981	II	III	IV	I	II	III	IV	I	II
Average percent adjustment (including no change):														
All industries	8.0	8.2	9.1	9.9	9.5	3.3	3.5	1.3	1.7	3.2	3.3	1.5	1.0	1.9
Manufacturing	8.4	8.6	9.6	10.2	9.4	3.4	2.9	1.7	2.3	2.4	3.1	1.9	.9	.9
Nonmanufacturing	7.6	7.9	8.8	9.7	9.5	3.2	4.0	1.1	1.2	3.8	3.4	1.1	1.0	2.6
From settlements reached in period	3.0	2.0	3.0	3.6	2.5	1.0	1.7	.5	.4	1.1	.5	.4	.2	.3
Deferred from settlements reached in earlier period	3.2	3.7	3.0	3.5	3.8	1.4	1.2	.3	.5	1.4	1.5	.4	.6	1.3
From cost-of-living clauses	1.7	2.4	3.1	2.8	3.2	.8	.7	.6	.7	.7	1.2	.6	.3	.2
Total number of workers receiving wage change (in thousands)[1]	—	—	—	—	8,848	—	—	—	3,895	4,701	4,304	3,225	2,865	3,300
From settlements reached in period	—	—	—	—	2,270	—	—	—	579	909	540	604	199	407
Deferred from settlements reached in earlier period	—	—	—	—	6,267	—	—	—	866	2,055	3,023	882	1,038	1,629
From cost-of-living clauses	—	—	—	—	4,593	—	—	—	2,630	2,609	2,934	2,179	1,900	1,496
Number of workers receiving no adjustments (in thousands)	—	—	—	—	145	—	—	—	4,937	4,092	4,426	5,566	5,767	5,304

[1] The total number of workers who received adjustments does not equal the sum of workers that received each type of adjustment, because some workers received more than one type of adjustment during the period.

p=preliminary.

WORK STOPPAGE DATA

Work Stoppages include all known strikes or lockouts involving 1,000 workers or more and lasting a full shift or longer. Data are based largely on newspaper accounts and cover all workers idle one shift or more in establishments directly involved in a stoppage. They do not measure the indirect or secondary effect on other establishments whose employees are idle owing to material or service shortages.

Estimates of days idle as a percent of estimated working time measures only the impact of larger strikes (1,000 workers or more). Formerly, these estimates measured the impact of strikes involving 6 workers or more; that is, the impact of virtually *all* strikes. Due to budget stringencies, collecuon of data on strikes involving 6 workers or more was discontinued with the December 1981 data.

35. Work stoppages involving 1,000 workers or more, 1947 to date

Month and year		Number of stoppages		Workers involved		Days idle	
		Beginning in month or year	In effect during month or year	Beginning in month or year (in thousands)	In effect during month (in thousands)	Number (in thousands)	Percent of estimated working time

SALES PUBLICATIONS

BLS Bulletins

Employee Benefits in Medium and Large Firms, 1981. Bulletin 2140, 47 pp., $4.75 (GPO Stock No. 029-001-02711-7). The third in an annual series, this survey of employee benefit provisions provides representative data for 21.5 million full-time employees in a cross-section of the Nation's private industries in 1981. It was designed to furnish the Office of Personnel Management with information on benefits of private sector employees in order to compare them with benefits of Federal workers.

Area Wage Survey Bulletins

These bulletins cover office, professional, technical, maintenance, custodial, and material movement occupations in major metropolitan areas. The annual series of 70 is available by subscription for $90 per year. Individual area bulletins are also available separately.

Billings, Montana, Metropolitan Area, July 1982. Bulletin 3015-26, 25 pp., $3.50 (GPO Stock No. 029-001-90146-1).

Greenville-Spartanburg, South Carolina, Metropolitan Area, June 1982. Bulletin 3015-23, 39 pp., $4.50 (GPO Stock No. 029-001-90142-9).

New York, New York-New Jersey, Metropolitan Area, May 1982. Bulletin 3015-24, 43 pp., $4.50 (GPO Stock No. 029-001-90143-7).

Periodicals

CPI Detailed Report, June. Comprehensive report on price movements for the month, questions and answers on upcoming changes in the measurement of homeownership costs, statistical tables, charts, and technical notes. 109 pp., $3.50 ($20 per year).

Current Wage Developments, July. Includes employee wage and benefit changes and collective bargaining settlements in June and a special report on the Employment Cost Index for March of 1982. 66 pp., $2.50 ($14 per year).

Employment and Earnings, August. Covers employment and unemployment developments in July, plus regular statistical tables on national, State, and area employment, unemployment, hours, and earnings. 124 pp., $3.75 ($31 per year).

Producer Prices and Price Indexes, June. Includes a comprehensive report on price movements for the month, information on the sample revision for steel mill products, plus regular charts, text, tables, and technical notes. 111 pp., $3.25 ($20 per year).

Mailgram Service

Consumer price index data summary by mailgram within 24 hours of the CPI release. Provides unadjusted and seasonally adjusted U.S. City Average data for All Urban Consumers (CPI-U) and for Urban Wage Earners and Clerical Workers (CPI-W). (NTISUB/158). $125 in contiguous United States.

Microfiche

Employment and Unemployment in States and Local Areas:
1978, BLS/LAUS/AR-82/04.
1979, BLS/LAUS/AR-82/03.
Provides benchmarked monthly estimates of the labor force, employment, and unemployment for States, labor market areas, counties, and county equivalents. Part of a subscription series, "Local Area Unemployment Statistics," available monthly: Domestic—$50 a year; Foreign—$62.50 a year.

Labor Month In Review

EARNINGS GAP. Commissioner of Labor Statistics Janet L. Norwood was the opening witness at congressional hearings exploring pay differences between women and men. Here are excerpts from the commissioner's testimony.

In 1939, median earnings for women who worked year round, full time were 58 percent of the median earnings for men. Similar figures for 1981, the latest period for which earnings over an entire year are available, show women's earnings at 59 percent of the median for men. Over the long term, the ratio has remained relatively unchanged.

The Current Population Survey data on weekly earnings show a similar ratio. The most recent figures for the second quarter of this year show median weekly earnings for full-time wage and salary workers were $370 for men and $240 for women, or 65 percent of men's earnings. Comparable figures 10 years ago were $168 for men and $106 for women, a 63-percent ratio.

Educational influence. For women as well as men, more years of schooling usually translate to higher annual earnings. Median earnings for women college graduates who worked all year at full-time jobs were 45 percent more than for women whose formal education terminated with high school graduation, and 80 percent more than for those who had not completed high school. For men, the proportions were similar. However, at every level of educational achievement, women's median earnings continued to lag far behind men's earnings. On average, whether college graduates or high school dropouts, women earned about 60 cents for every dollar their male counterparts were paid.

This 60-percent ratio in the national aggregate data shows a female-male wage gap of about 40 percent.

Human capital influence. A large body of "human-capital" research is available. Many of these studies focus on characteristics of individual workers such as age, years of schooling, labor force experience, and so forth. A review of this research by a recent National Academy of Sciences panel shows that in the studies reviewed, worker characteristics account for at most 44 percent of the female-male earnings gap.

These estimates are somewhat sensitive, of course, to the accuracy with which the characteristics are measured. In particular, years of labor force experience are usually approximated by calculating experience as the number of years since the completion of schooling. For persons with interruptions in their work experience—which includes more women than men—experience estimated in this way will be overstated. The measurement of this factor alone has been the subject of a number of studies (not all of which agree with each other) in the past 10 years.

Two BLS economists, Wesley Mellow and B. K. Atrostic, have found that, when a different measure more nearly approximating actual work experience is used while holding unchanged other characteristics, the estimated female-male wage gap is reduced by about 7 percentage points.

A fairly consistent finding from many studies of microdata is that the estimated female wage gap is reduced—but not eliminated—as more economic and demographic factors are introduced into the analysis. Another recent study by Mellow, for example, estimates the female-male wage gap at 27 percent when the following variables are held constant: area, occupation, industry, union, part-time status, and estimated labor force experience.

Occupational influence. In addition to the "human capital" that individual workers bring to their jobs, it is quite evident that earnings are highly correlated with the occupation and the industry in which a worker is employed. And we know that working women are far more concentrated in generally low-paying occupations in low-paying industries.

Recent CPS median earnings data (for the second quarter of 1982) show that in the female-intensive clerical field, women working full time earned $236 a week, compared with $337 for men. At 70 percent, the current ratio of women's to men's median earnings was practically the same as it was 10 years ago. But women clerical workers are far more likely to be in lower paying groups of the occupations, such as secretaries, typists, cashiers, and bookkeepers.

The same sort of pattern emerges when we look at both ends of the pay spectrum for men and women. A recent study by BLS demographer Nancy Rytina examines wage and salary earnings in 250 occupations. Seven of the twenty lowest paying occupational groups were the same for both men and women: farm laborers, food service workers, cashiers, waiters and waitresses, cooks, nurses' aides and orderlies, and bartenders. The female-male earnings ratios in these occupations ranged from 72 percent for waiters and waitresses to 92 percent for cashiers. With the exception of farm laborers and bartenders, all of these occupations were both female intensive and relatively low paying.

When we compare median earnings for the high-paying occupations which men and women hold in common, we find that median earnings of women are substantially less than for men.

The pay differences between men and women in [high-paying] occupations tend to be somewhat greater than among men and women in low-paying jobs. The median earnings ratios ranged from 64 percent for personnel and labor relations workers (the greatest difference) to 82 percent among operations and systems analysts (the smallest difference).

Commissioner Norwood's full testimony appears in BLS Report 673, *The Female-Male Earnings Gap: A Review of Employment and Earnings Issues.* Single copies are available without charge from BLS Inquiries and Correspondence Section, 441 G St. N.W. Washington, D.C. 20212. □

Labor force data from the CPS to undergo revision in January 1983

BLS statistics in 1983 will include members of the Armed Forces stationed in the U.S. and will drop classification of workers as 'blue collar' or 'white collar,' substituting a new occupational system

JOHN E. BREGGER

Beginning with data for January 1983, the Bureau of Labor Statistics will make changes in presentation, classification, and estimating procedures in labor force data derived from the Current Population Survey (CPS). This article reports on the nature of and reasons for the changes.

In any economic time series, there is an inevitable conflict between the need for maintaining a consistent data series for historical analysis and the need to introduce change to reflect new concepts and definitions or improvements in survey operations. It is the practice of the Bureau of Labor Statistics, whenever changes become necessary, to introduce them with full explanations, including the reasons for undertaking them and a description of their impact. Moreover, to the maximum extent possible, historical data are revised in order to maintain temporal consistency.

The CPS is one of the most valuable sources of economic time series data, having provided essentially consistent measures of the labor force status of the civilian population for more than 40 years. In addition to aggregate measures of economic performance, data collected and published monthly include a rich array of demographic, occupational, and industrial detail, allowing for many cross-classifications.[1] CPS changes have resulted from such events as the availability of data from the most recent decennial census; recommendations by commissions appointed to review the survey and its underlying concepts; and improvements in such areas as survey design, questionnaire content, and industry or occupational classification systems. The most recent change was the introduction of 1980 census population figures into estimation procedures.[2]

Several other changes in the CPS are also planned for the 1980's. Of major significance is a comprehensive redesign of the entire sample—a process that occurs after every decennial census—and a possible revision in the CPS questionnaire. In the more immediate future, there are four separate modifications that will become effective with January 1983 data. These are:

- Persons in the Armed Forces stationed in the United States will be included in the national labor force and employment totals and thus in the base for the overall unemployment rate.
- All occupational detail in the CPS will be coded according to the classification system developed for the 1980 decennial census, which evolved from the 1980 Standard Occupational Classification system (SOC).
- In terms of racial classification, data will be published for the "black" group instead of for the broader "black and other" category.
- Revised "first-stage ratio estimates" based on the 1980 Census of Population and Housing will be introduced into the estimation procedures.

These changes affect the data in different ways. The first and third relate to data presentation, the second is

---

John E. Bregger is Chief, Division of Employment and Unemployment Analysis, Bureau of Labor Statistics.

one of classification, and the last one updates the estimating procedures. The nature and potential impact of these changes are discussed below.

Resident Armed Forces

Over a 14-month period during 1978–79, a presidentially appointed, congressionally mandated panel of experts convened to examine "procedures, concepts, and methodology involved in employment and unemployment statistics and suggesting ways and means of improving them."[3] Known as the National Commission on Employment and Unemployment Statistics, this nine-member panel made many recommendations for improving the Nation's labor force statistics (in its final report, *Counting the Labor Force*).[4] One of these recommendations was to treat members of the Armed Forces stationed in the United States as "employed" in national statistics, because joining the military was (and still is) voluntary and thus represents a viable job market alternative.[5] This recommendation was subsequently accepted by Secretary of Labor Raymond Donovan in his final report on the Commission's recommendations.[6]

At present, there are nearly 1.7 million persons in the Armed Forces stationed in the United States, out of a total of 2.2 million. In keeping with the Commission's recommendation, effective with January 1983 data, they will be included in the totals for labor force and employment and thus affect the calculation of the overall unemployment rate as well. Also, separate data for all men and women 16 years and over will include the resident Armed Forces counts. Data for all other worker groups, such as for specific age-sex groups and racial detail, will continue to be on a civilian basis only, because, although data for the resident Armed Forces total and for both sexes are available from the Department of Defense as far back as 1950, there is considerably less information available for individual age groups and by race. Consistency over time will be maintained through revision of historical totals back to 1950 and otherwise by sustaining all civilian data series.

In addition to increasing the magnitudes of the labor force and total employment, the addition of the resident Armed Forces will also reduce the overall unemployment rate—contrasted with the civilian labor force-based measure—although by only one- or two-tenths of a percentage point. For example, the 1981 annual average unemployment rate will be 7.5 percent, compared with the civilian-based 7.6 rate. The total rate for men will be reduced by one- to three-tenths of a point, depending on rounding, whereas the women's rate typically will be unaffected.

New occupational classifications

In 1977, following a lengthy period of careful examination by many experts in the field of occupational classification, the first edition of a standardized classification system of occupations was introduced.[7] Whereas such a system has long existed for industries, this was the first for occupations. Among other things, the Standard Occupational Classification (SOC) was "designed for use in statistical analysis and presentation about occupations,"[8] and it also served to reconcile heretofore diverse classification systems, such as the Census system and Dictionary of Occupational Titles. The SOC was revised somewhat in 1980, to take into account the comments of users resulting from the issuance of the 1977 manual and to "assure that the Bureau of the Census could incorporate the changes as part of its tabulation program for the 1980 census."[9] The Census Bureau adapted the SOC for use in the 1980 census. This SOC-Census hybrid represents a comprehensive revamping of the occupational classification system used for prior censuses as well as that currently in the CPS, in that much of the nomenclature and recognizable groupings have been completely revised.

Because of the conversion of occupational classification for the 1980 census, it was clear that the revised classification had to be introduced into the CPS as soon as possible, and January 1983 has been chosen as the effective date. The change will be dramatic. Such commonly used identifiers as white-collar and blue-collar and professional and technical, craftworkers, and operatives will disappear. Moreover, so many classification changes will occur that reconstruction of these groupings will be equally impossible. Thus, there will be no long-term consistent time series for large occupational groupings, and seasonal adjustment cannot be undertaken for several years.

Exhibit 1 presents old and new occupational titles at the broadest and second broadest aggregations.[10] Based on the groupings shown, one might conclude that SOC titles could be combined so as to retain the white-collar and blue-collar categories; but this is not being done for a variety of reasons. For one, although not specifically stated, the framers of the SOC had explicitly intended to finally purge these titles because of the favorable impression given by "white-collar" versus the more pejorative notion of "blue-collar." In reality, some parts of the old clerical and sales occupations were considerably below both of the other white-collar as well as some blue-collar groups—in terms of earnings or prestige. Another misleading aspect of both white- and blue-collar categories in the present census classification system is the unevenness and largely misunderstood aspects of each; among other things, they are incorrectly assumed by many to exhaust occupational coverage (there are also the service and farm groupings). Finally, while it might appear that the first two categories in the "broad grouping" of the modified SOC correspond to white-collar and the fourth and fifth to blue-collar, the specific

Exhibit 1. A comparison of 1980 decennial census occupational nomenclature to be used in 1983 with the 1970 census system

Broadest groupings

New	*Pre-1983*
Managerial and professional specialty Technical, sales, and administrative support Service Precision production, craft, and repair Operators, fabricators, and laborers Farming, forestry, and fishing	White-collar Blue-collar Service Farm

Major occupational groups

New	*Pre-1983*
Executive, administrative, and managerial Professional specialty Technicians and related support Sales Administrative support, including clerical Private household Protective service Service, except private household and protective service Precision production, craft, and repair Machine operators, assemblers, and inspectors Transportation and material moving Handlers, equipment cleaners, helpers and laborers Farming, forestry, and fishing	Professional and technical Managers and administrators, except farm Sales Clerical Craft and kindred Operatives, except transport Transport equipment operatives Nonfarm laborers Private household Other service workers Farmers and farm managers Farm laborers and supervisors

content of the various component occupations have been changed so that the data would not match.

In an effort to mitigate the inescapable problems that will ensue from introducing a totally new occupational classification system into the CPS, the Census Bureau is coding 20 percent of the monthly records for 1982 on the new system. This will permit a limited crosswalk between the two systems through a matrix of the broad groupings shown in exhibit 1. The more desirable matrix of the present 428 three-digit occupations with the comparable grouping of 503 in the SOC-Census hybrid will not be operationally feasible.

BLS will initiate publication of the new occupational data in *The Employment Situation* press release for January 1983 and in the February 1983 issue of *Employment and Earnings*; the latter is also expected to contain a rundown on some of the impacts on CPS occupational data. Whereas comparison of data with the past, to include a continuation of trends, will not be possible, it is felt that the vast improvements brought about through the availability of a universal classification system will greatly outweigh these problems as time goes by.

Conversion to black only data

Traditionally, racial data have been presented for two groups, "white" and "black and other" (formerly termed "nonwhite"). Historically, blacks have predominated the latter category—more than 92 percent of the black and other population in the 1960 census and 89 percent in 1970—such that the "black and other" group was deemed to portray adequately the situation among blacks. But in recent years the population of the "other" group—mostly Asian and Pacific Islanders, American Indians, and Alaskan natives—has been expanding at a greater pace, and, by the 1980 census, the black proportion of the "nonwhite" population had dropped to 85 percent. Moreover, labor market and other characteristics vary considerably by race. For example, in 1981, the annual average unemployment rate for blacks was 15.6 percent, compared with 14.2 percent for black and other; the other races rate was significantly lower.

In view of the lower proportion of blacks within the black and other population, which has resulted in a situation whereby the larger group is now less representative of the status for blacks, it is fitting that the presentation of these statistics be converted to black (only). This has already been accomplished on a limited basis, with the publication of the major employment status categories by age and sex for blacks in *The Employment Situation* press release in 1982. Beginning in 1983, there will be a more comprehensive conversion, as all published tables containing racial data will show "black" instead of "black and other" statistics. The other races classification is too small—and is not controlled to independent population weights in the estimation process—to meet reliability standards for publication. (Data for the group can be ascertained through subtraction.) Data for blacks are available back to 1972 and can be provided to interested users upon request. At the same time, BLS will retain the capacity to produce data for the "black and other" group.

Revision of first-stage ratio estimator

Information from the decennial population censuses figure prominently in the CPS design and estimating procedures. To begin with, the censuses form the basis for the sample design and selection for the ensuing 10 years after the census materials become available. Moreover, the population estimates carried forward from the censuses are used as weights to which the sample estimates are "blown up" to represent the Nation. As indicated earlier, the weights based on the 1980 census population figures were introduced into the CPS effective with January 1982 data; technically, this weighting occurs in what is known as the "second-stage ratio estimate" and is done for each of 64 age-sex-race groups making up the population 16 years of age and over. There is also a "first-stage ratio estimate," which has continued to be based on the 1970 census. Effective with data for January 1983, data from the 1980 census will be used in the development of first-stage ratio estimates as well.[11]

The first-stage adjustment concerns that portion of the 629 sample areas that have been chosen to represent other areas not in the sample—the remainder represent themselves. These "nonself-representing" areas are adjusted so as to correct for differences existing at the time of the most recent census between the distribution by race and residence of the population in these areas and the known race-residence distribution in the portions of the census region or State represented by these areas. The procedure is applied at two geographic levels: by region—Northeast, North Central, South, and West—and for each of the 46 States that contain nonsample areas. The regional adjustment is performed by metropolitan-nonmetropolitan residence and race, while the State adjustment is done by urban-rural status and race. The introduction of the 1980 census information for regions and States could well produce a "bump" (break in series) in some of the estimates. The nature and extent of any discontinuity will not be known until the time of the introduction of the revised first-stage factors but will clearly be quite small vis-a-vis the effect of the 1980 census-based second-stage factors.[12] Indeed, it is possible that the effects will be limited to internal estimations, such as farm-nonfarm and metropolitan-nonmetropolitan data, while not affecting broader totals. Again, any impacts will be described in a special article devoted to the changes being introduced into the January 1983 CPS, that will appear in the February 1983 issue of *Employment and Earnings*.

IN SUMMARY, there will be four distinctly separate changes introduced into the 1983 CPS that will affect the data. One change—adding the resident Armed Forces to the statistics—was recommended by the National Commission on Employment and Unemployment Statistics, which also acknowledged the necessity for the second change discussed—the revision of all occupational data based on the Standard Occupational Classification system.[13] The third change—publishing data for "black" instead of "black and other" workers—relates to data presentation rather than revision but is very important in terms of usage. The final change—revising the first-stage ratio estimates—is technical and results from the availability of information from the 1980 decennial census. All changes are made so as to improve either the basic data or enhance our use and understanding of the data. □

FOOTNOTES

[1] The primary compendium of monthly, quarterly, and annual data is the BLS publication *Employment and Earnings*. The explanatory notes section in the back of each issue describes the survey and nature of the data collected.

Better measures of service employment goal of Bureau survey redesign

The volatility and small size of companies, coupled with nontraditional payroll practices, complicate efforts to develop more reliable data on employment, earnings, and hours of work

THOMAS J. PLEWES

The problem of measuring economic activity in the growing service-producing sector of the economy has posed an acute and continuing challenge to those agencies responsible for providing economic data. The service sector is characterized by diverse activities loosely aggregated under the service-producing classification; by a large number of preponderantly small companies that enter and exit the market with some frequency; and, consequently, by a unique set of problems associated with identification, classification, collection, and estimation of economic information.

This article focuses on the challenges in measuring employment, hours, and earnings in this large and dynamic sector of the economy. First, historical trends in the composition of the industrial employment base are discussed to illustrate both the strong growth of this sector and the reason for concern over the adequacy of measurements. A description of the Bureau of Labor Statistics' primary sources of current data on employment, hours, and earnings, and their importance in tracking economic developments, sets the stage for exploring, in more detail, the sources of measurement problems. Some problems stem from the nature of employment practices, from the conduct of the surveys, and from employer recordkeeping procedures; others relate to the relative instability of the small establishments that characterize the sector. The final section outlines initiatives which have been undertaken by the Bureau to redesign the Current Employment Statistics Survey, the major source of employment and earnings measures by industry, to ensure that firms in the service sector are appropriately represented by the survey, and that survey operations are tailored to the special needs of service-sector employers in order to gain their cooperation in the survey.

Why the interest in service employment

In the United States, as in other industrialized nations, the long-term shift from an agricultural, to a goods-producing, to a service-producing economic base has emerged. The strength and pervasiveness of this trend, which has particularly accelerated over the last two decades, has been extensively documented else-

---

Thomas J. Plewes is Assistant Commissioner for Employment Structure and Trends, Bureau of Labor Statistics. This article is based on a report prepared for the Organization for Economic Cooperation and Development's Working Party on Employment and Unemployment Statistics. Mary Kay Rieg of the *Review* staff provided special editorial assistance.

where.[1] Nonetheless, some of the highlights of this evolution are quite significant and worth stressing:

- Since 1920, the service-producing share of nonagricultural employment has gone from 53 percent to 72 percent. Two divisions showed significant growth—the service industries and government. (See table 1.)
- This evolutionary shift in the industrial complexion accelerated during the Great Depression, dampened as the Nation turned to hard-goods production during World War II, but has resumed a steady pace since the mid-1940's.
- Over the past two decades, some 86 percent of job growth in the economy has occurred in the service-producing sector. By mid-1982, this sector provided 74 percent of all jobs, up from 62 percent in 1960.
- During recessionary periods, the service-producing sector has shown remarkable resilience while the goods sector has borne the brunt of the economic declines. This relative immunity from downturn has also been evidenced in the most recent recessionary period.[2]
- The shift from a goods to a service economy represents changes in the U.S. economy of historic proportions. It has been influenced by such factors as the increase in demand for consumer services previously produced outside the measured market economy, the increase in the demand for leisure goods, shifts from internal to external sources for business services (such as marketing, accounting, and the like), and the changing nature of international trade. In turn, the shift has had a pronounced influence on the character of the labor force, particularly in opening opportunities for women. Over the past two decades, women's share of service-producing employment has expanded from 40 to 50 percent, accounting for 65 percent of the employment expansion in the sector.

Review of data sources

The Bureau of Labor Statistics maintains three primary sources of data on employment, hours, and earnings in the service sector. Each has its own strengths and weaknesses.

The establishment survey. The Current Employment Statistics Survey, commonly referred to as the establishment survey, collects payroll data from nonagricultural employers for the pay period including the 12th of each month. The survey, conducted by mail, obtains summary data on total numbers of employees, including women workers and production or nonsupervisory workers. In addition, summary data on the payroll and hours (paid for) of production or nonsupervisory workers are collected in order to compute average hourly earnings, and average weekly hours and earnings. Overtime hours data are collected for production workers in manufacturing. Employer participation in the survey is voluntary.

Table 1. Employment composition of goods- and service-producing sectors, 1920 and 1981

[Numbers in thousands]

Divisions	1981 employment	Percent distribution	
		1920	1981
Nonfarm economy	91,543	100.0	100.0
Goods-producing sector	25,672	46.7	28.0
Mining	1,104	4.5	1.2
Construction	4,307	3.2	4.7
Manufacturing	20,261	39.0	22.1
Service-producing sector	65,871	53.3	72.0
Transportation and public utilities	5,151	14.6	5.6
Trade	20,738	16.3	22.7
Wholesale	5,343	—	5.8
Retail	15,395	—	16.8
Finance, insurance, and real estate	5,331	4.3	5.8
Services	18,598	8.6	20.3
Government	16,054	9.5	17.6
Federal	2,772	—	3.0
State and local	13,282	—	14.5

The establishment survey is conducted as a cooperative Federal-State program with State Employment Security Agencies collecting most of the data. The employer's microdata can thus be used by the States to prepare local estimates (currently available for 50 States and more than 200 Standard Metropolitan Statistical Areas) and, at the same time, by the Bureau of Labor Statistics to prepare national estimates. Duplication of data collection at the Federal and local levels is avoided through this cooperative arrangement.

The establishment survey is the largest monthly survey in the field of economic statistics, with an active sample of 180,000 establishments reporting data covering about 35 percent of total nonagricultural employment in the United States. Data are published for more than 500 separate industries at the national level, and in varying degrees of industry detail at the State and Standard Metropolitan Statistical Area levels. The survey provides monthly measures of total employment and numbers of women and nonsupervisory workers for 155 service-producing industries at the national level. This represents 30 percent of the 567 service-producing industries designated in the U.S. Office of Management and Budget's 1972 Standard Industrial Classification System. Estimates of average weekly earnings, average weekly hours, and average hourly earnings are produced for nonsupervisory workers in most of these industries.

The data collected in the Bureau's monthly survey of employment, hours, and earnings have served as a primary source for tracking the growth of the service-producing sector. Thus, in and of themselves, these data are called upon to portray trends with accuracy and timeliness as a basis for economic decisionmaking. However, the data have critical secondary uses which also fuel the demand for reliable reporting and accurate measurement of employment, hours, and earnings in the service sector.

Within the Bureau, for example, the data have the following major uses:

- *In productivity measurement*: Monthly total hours by industry detail and production-worker employment data are key inputs to productivity measurement and the quarterly productivity estimates. The annual employment and hours data for detailed industries are used for developing labor inputs for measures of output per employee hour.
- *In occupational employment projections*: National employment data by industry detail are projected forward and occupational staffing patterns of the industries are applied to those projected industry levels to produce projected occupational patterns.
- *In economic growth studies*: A key input into the BLS economic growth model is annual employment data by detailed industry.
- *In development of subnational unemployment statistics*: The monthly employment data are used both by the BLS and the State agencies as the source of employment data for those subnational areas for which the household survey, discussed below, fails to provide reliable estimates. Currently, the unemployment rates for 40 States and about 200 areas are computed using these survey results as a key input.
- *In occupational health and safety statistics*: Detailed annual industry employment levels are used for computing total injury rates, with actual injury experience based on an annual survey and administrative records.

Other Federal agencies also use the service sector data extensively:

- *In personal income and gross national product estimation*: The U.S. Department of Commerce's Bureau of Economic Analysis uses the monthly employment and earnings series as a key input for estimating the wage component of these economic measures.
- *In management of trade policy*: Detailed industry employment trends are used to determine job loss associated with increased imports.

In addition to these critical, continuing government uses of the data, the private and public sectors also rely on the survey results for: marketing studies; economic research and planning; government funding and policy analysis; regional analysis; industry studies; plant location planning; wage negotiations; and adjustment of labor costs in escalation of long-term contracts.

The Current Population Survey. This monthly survey collects data on employment status directly from individuals in households and provides information on the demographic, occupational, and other characteristics of the employed, the unemployed, and persons not in the labor force. The household survey is conducted by the Bureau of the Census each month for BLS, providing data for the Nation and the 10 largest States.

Each month, 60,000 housing units are eligible for interview, by personal visit or by telephone. Information is gathered on the personal characteristics of all members of the household 16 years of age and over and on their labor force status during the survey week (week including the 12th of the month). This makes possible detailed tabulation and publication of labor force data by demographic characteristics.

The results of the establishment and household surveys are published and analyzed together each month, 3 weeks after the survey reference week. Estimates from both surveys generally show the same trends in employment. By publishing the results of both surveys together, the current analysis of the Nation's employment situation is greatly enhanced, with the household survey providing demographic detail and the establishment survey providing industry detail.

Each month, the household survey provides employment, unemployment, and labor force data for nine service-producing industries. The emphasis of the monthly data is to provide the basic types of estimates on labor force status by an extensive array of demographic characteristics. On an annual basis, employment data from the household survey are published for 116 service-producing industries along with the percentages of employed women and members of racial minorities.

Administrative establishment files. Unemployment insurance (UI) laws administered by State Employment Security Agencies cover almost every employer unit. The States require each unit (establishment) to provide a quarterly report on employment and wages of its work force and to pay a tax into the unemployment trust fund. As a byproduct of this administrative reporting system, and the Federal-State cooperative relationship, BLS obtains from each State a virtual census of establishments, and their employment and wages, on a quarterly basis. By assigning industry and location (county) codes to each establishment's record, the employment and wage data can be summarized by size-of-employment class, within industry and county, and through successive aggregations, to Standard Metropolitan Statistical Area, State, regional, and national totals.

What these data lack in timeliness, they make up for in comprehensiveness. Because of the large number of UI reporting units (4.5 million), coupled with the lag in the required payment of taxes, and associated data entry, correction, and tabulation workloads, the UI data are generally not available in summary form until 6 to 9 months after the end of each quarter. Nevertheless, because of the comprehensive nature of the data and the potential for dissaggregation to complete industry and county detail, this data base is extremely important. It serves as the foundation of the establishment survey—first, as the sample frame from which States solicit survey respondents and second, as a benchmark to adjust national and subnational employment levels annually.

Because the UI data represent nearly a universe of wage and salary workers in nonagricultural industries, employment (for each month of the quarter), number of reporting units, and total quarterly wages can be tabulated for each quarter and presented in complete industry detail (567 industries in the service-producing sector) at all levels of geographic aggregation from the county (3,100) level up to national totals. The industry statistics can be tabulated by size of firm and type of ownership (private, and Federal, State, and local government) as well. The only limit to disaggregation of the UI data base is the requirement that confidentiality be provided for any reporting unit. Therefore, publication rules to prevent disclosure are rigorously adhered to.

While the focus of the analysis in this article is primarily on measures of employment, hours, and earnings on a current basis in industry detail, it is the availability of the UI administrative record of all employing units in the Nation—tracking their birth, growth, and demise—that provides us with the information to both design the Current Employment Statistics Survey and to adjust that design as the nature of the economy changes. Very little nonagricultural wage and salary employment escapes coverage under the UI laws. Of almost equal importance, the UI reporting system is able to identify establishment deaths and purge the appropriate records from the files on a timely basis.

Measurement problems

The unique measurement problems of the service-producing sector stem both from the nature of the establishments and from the types of survey operations used to gather data in the Current Employment Statistics program. As previously indicated, the industry statistics on employment, hours, and earnings are gathered monthly on a voluntary basis, using a mail questionnaire to obtain data from establishment payroll records.

Sampling difficulties. For a variety of reasons, the one characteristic of an establishment that appears to be most telling of its likelihood to voluntarily respond in a government survey is its size, in terms of the number of employees on the payroll. As a consequence, experience has shown that it is more difficult to implement optimal sample designs, which require certain response rates, in those industries which are characterized by small firms. Small firms predominate in many of the industry divisions in the service sector, as shown by the distribution of the survey's sample by size of establishment and sample coverage by industry division in table 2. With the exception of government, portions of transportation and public utilities, and a few individual service industry groupings, such as banks and hospitals, the sample in the service sector falls short of representation in the smallest size categories.

Historically, this has been more of a problem in the service-producing sector than in the goods-producing sector. The reasons are shown in table 3, which arrays total employment by size class for these sectors. Using 250 employees as a cutoff point to distinguish between small and large employers, employment in the goods-producing sector was split 49 to 51 percent in 1980. In the service-producing industries, the split between small and large was 70 to 30 percent, reflecting the greater proponderance of small employers. Data from the UI administrative data base, shown in table 4, provides further evidence of the concentration of employment in the smaller firm classes in selected service industries.

Employment practices. The establishment survey of employment, hours, and earnings currently is designed to portray the level of and change in activity in establishments which have fairly traditional employment practices. The assumptions incorporated into the survey design and estimation procedures include a relatively stable work force that expands or contracts with the pace of economic activity in the short term, and with technological innovations in the long term; a normal pattern of regular hours and overtime payment that expands or contracts in the short term with the level of economic activity; and a standard work force composition which assumes that the worker has some permanent attachment to the employing establishment.

Analysis of the employment practices of service industries indicates a number of departures from traditional employment practices. For example, statistics on labor turnover rates by industry indicate that turnover is highest among those industries that are characterized by a preponderance of small firms with relatively large numbers of easy entry, low-skill occupations. According to a 1980 study by Malcolm Cohen and Arthur Schwartz, the service-producing industries with the highest labor turnover rates were: automotive dealers and service stations; automotive repair, services, and garages; water transportation; real estate; business services; motion pictures; hotels and other lodging places; amusement and recreation services; and eating and drinking places.[3] These industries rank among the lowest in terms of average earnings, which is consistent with their high proportions of low-skill jobs.

Average weekly hours have generally been declining for these industries for many years, and are very low relative to those in most other industries. This largely reflects a growing practice of part-time employment in these industries. Data from the household survey, shown in table 5, provide direct evidence of the dramatic growth in part-time employment in many of the service-producing industry divisions relative to the goods-producing divisions. (In the household survey, a person is counted as part time if he or she normally works less than 35 hours.) The proportion of part-time workers in the goods-producing industries has hardly changed over time, averaging a low 4.5 percent in 1981. In contrast, the proportion of part-time workers has increased for almost all of the service-producing industries, and averaged 20.7 percent in 1981. The highest rates are in retail trade (36.0 percent), personal services (27.2 percent), entertainment and recreation services (35.0 percent), and medical, except hospital, services (26.1 percent).

Generally, the characteristics of high labor turnover, low earnings, low skill requirements, and high proportions of part-time workers seem to depict a rather loose or casual bond between the employer and employee in the service sector. This loose bond, in turn, contributes to deviations from traditional payroll practices which are assumed in survey definitions, and undoubtedly

[1] Excludes railroads.

[2] Sample total in large size class includes combined units of telephone companies reporting to BLS under special arrangements.

NOTE: Because of rounding, sums of individual items may not equal totals. Data are classified according to the U.S. Office of Management and Budget's 1972 Standard Industrial Classification system.

adds to the difficulties that employers have in reporting in government surveys.

Data collection problems. In the final analysis, the kind of data that might be obtained in a survey operation is constrained by the amount of information that the respondent has at ready access. This is certainly the case with the establishment survey of employment, hours, and earnings, which has historically been keyed to the type of information readily available from the payroll records of responding firms. The experience of the Bureau and the cooperating State agencies is that establishments will report, under our strict pledges of confidentiality, information that would normally be considered privileged and proprietary, but only if it is conveniently and readily accessible. If the information request goes much beyond the normal recordkeeping practices of the firm, both overall response rates and responses to particular data items will suffer.

As a part of an overall review of the establishment payroll survey, BLS conducted two interview surveys with employers during 1981. The first sought to determine what data elements are readily available from employer payroll records on a monthly basis, while the second concerned itself with the reasons why employers are unable or reluctant to provide the requested data.

The majority of respondents indicated that the information requested each month was readily available. However, the proportion of manufacturing respondents who had easy access to such records was higher than the proportion of service respondents. This shows up in a rather significant difference between the service and manufacturing employers regarding their willingness to cooperate with the survey. For example, 45 percent of service-industry employers cited lack of time or resources to complete the BLS 790 survey form, compared with 19 percent of manufacturing employers.

The BLS 790 questionnaire requests a count of nonsupervisory workers, together with their payroll and paid hours. The interviews revealed that 31 percent of the service-industry employers who are reporting monthly information to BLS do not differentiate between supervisory and nonsupervisory workers in their payroll records. Because many of these establishments are small, the respondents are able and willing to make the necessary adjustments for BLS. However, 64 percent of employers who refused to cooperate in the survey claimed that they maintain only one payroll figure for all their employees and are unable to provide the requested nonsupervisory breakouts.

Another problem encountered in the interviews was that a significant proportion—19 percent—of service industry employers use an outside accounting service for preparing payrolls and payroll summaries, while only 5 percent of manufacturing employers do so. The accounting services generally handle only mandatory government reports for their clients, and this would have a negative impact on responses to a voluntary questionnaire like the BLS 790.

Table 3. Distribution of employment by establishment size class, and sector, 1980

[Employment in thousands]

Size class	Private nonfarm sector		Goods-producing sector		Service-producing sector	
	Employment	Percent of total	Employment	Percent of total	Employment	Percent of total

NOTE: Based on coverage under State Unemployment Insurance Laws. Excludes railroads, some nonprofit institutions, and commission insurance salesworkers.

Table 4. Selected service industries with large concentrations of small establishments, 1980

Industry	Total employment	Percentage of employment in firms with —			
		Under 10 workers	10 to 49 workers	50 to 249 workers	More than 250 workers
Gasoline service stations	554,000	53	29	14	4
Eating and drinking places	4,481,000	14	42	28	16
Real estate agents	344,000	40	30	24	6
Laundry, cleaning, and garment services	356,000	28	36	30	6
Beauty shops	284,000	64	27	7	2
Automotive repair shops	351,000	62	33	4	1
Offices of physicians	739,000	56	31	9	4
Offices of dentists	336,000	80	18	1	1

In sum, many of the reservations voiced by respondents to the interview surveys related to the fact that small establishments, already burdened with mandatory government reporting, simply are unable or unwilling to add to their paperwork by filling out voluntary survey forms. Some large service-industry employers which might otherwise be willing to cooperate—such as hospitals or schools—frequently do not maintain records according to BLS definitions, and thus are unable to report the requested information.

New business formations. In the establishment survey, the direct measurement of employment growth due to new business formations is exceedingly difficult. The lead time necessary to prepare the universe listing of establishments from which to select new sample respondents practically assures that any new business establishment will be several months old before it has a chance of being in the sample. In most instances, the new business will have completed its initial hiring before it becomes a sample member. Once the new establishment is a sample member and has reported for 2 consecutive months, its month-to-month employment change will contribute to the calculation of the "link relative" that is applied to the previous month's employment estimate to derive the current month's estimate. The problem is that the initial hiring that occurred before the new business became a sample member is never reflected in the "link relative" calculation.

The inability to properly measure employment growth from business births creates a downward bias in the employment estimates, which accumulates each successive month after the most recent benchmark to employment levels from the UI administrative data base. The extent of the bias is directly proportional to the contribution of business births to the employment in a given industry.

In industries characterized by large employers, new entries are very rare and therefore contribute little if

Table 5. Percentage of part-time workers[1] by industry, selected years

[1] Voluntary part-time workers, plus workers on part time for economic reasons who usually work part time.

[2] Data not available.

anything to employment trends. Many of the service-producing industries, however, are characterized by small employers, with large numbers of business births and deaths. While the deaths are measured by the establishment survey, the births are not, and an adjustment to the sample trend must be made each month to correct for the bias. These "birth bias" adjustment factors may account for a large part of the estimated long-term employment growth of many of the service-producing industries.

The calculation of birth bias adjustment factors is straightforward. For each of the most recent 3 years, the employment estimate derived from the sample link relatives (with no bias adjustment) is compared to the benchmark level. An adjustment factor is then calculated so that its application each month thereafter will cumulatively add to the average amount that the three previous benchmarks were underestimated. For example, if the sample-derived employment estimate for an industry was lower than the employment benchmarks by 1.6, 0.8, and 1.2 percentage points for the most recent 3 years, the average downward bias is 1.2 percent. A factor of 1.0010 will then be applied to the link relative for each of the next 12 months so as to adjust by 1.2 percent over the year.

Because of the availability of annual benchmark employment levels, it is possible to measure the extent of the bias for each industry over time. We have observed that the contribution of the bias can change at different stages of the business cycle. The bias also has seasonal swings in certain industries, and can be sensitive to shocks to the economy, such as the 1973–74 oil embargo and the abnormally high interest rates of recent years. However, despite an ability to identify bias, the Bureau has not been able to develop procedures to fine-tune the bias adjustments on a current basis except in the construction division, which behaves with somewhat more predictability over the business cycle.

Redesigning the establishment survey

A review of the published output of the establishment survey as it is currently designed and operating puts into perspective the structural problem with the survey. As indicated in table 6, only 30.4 percent of the published industries are service producing, although 72.0 percent of the Nation's jobs are in these industries. A large part of this disparity arises because the Standard Industrial Classification system provides for more detail on goods-producing industries than on service-producing.

In addition to the problem of the coding structure, however, the establishment survey has been unable to produce data of publishable quality for much of the service-producing area because of the difficulty in obtaining employer responses and maintaining regular month-to-month reporting for a sufficiently large and representative sample in many of the component industries. The Bureau of Labor Statistics is now launching a major redesign of the survey which will deal directly with the problems that have prevented us from providing more reliable employment, hours, and earnings data for specific service-producing industries.

The sample frame. Because the UI administrative data base is unique in providing universal coverage of employers, we plan to continue and strengthen the link between the establishment survey and the administrative

Table 6. Distribution of industries by sector, according to SIC coding structure and as published by BLS

Divisions	1972 SIC structure		Published by BLS

Government	38	3.1	23	4.5	60.5

data base. Initially, for example, testing of alternative sample designs will be done by retrospective cross tabulation of employer data from the UI files. In this manner, we can evaluate the representativeness of various designs for estimating employment and wages by industry without having to collect additional data.

We also plan to review carefully the completeness of the UI data base by comparisons with other listings of employers, such as the Census Bureau's Standard Statistical Establishment List and the files maintained by Dun and Bradstreet as part of its credit rating operations. And, particularly because of the volatile nature of many of the small establishments in the service sector, we want to review and document the procedures used by the State Employment Security Agencies for processing establishment births and deaths.

Bias adjustment. As part of the redesign effort, we will attempt to reduce the amount of bias adjustment for establishment births required in the employment estimates. This will be accomplished through additional stratification of the estimating cell structure. In addition, we will be reviewing potential sources of new-firm data and testing the use of such information in our estimation system. We know that new business formations and their impact on current employment trends vary significantly during a business cycle for many industries. Further work will be done to document this and to arrive at an appropriate means of varying the bias adjustment factors on a current basis according to the stage of the cycle.

Examination of seasonality. Seasonal adjustment of the establishment data is performed annually using the X-11 ARIMA model. The model options for projecting the data series 1 year ahead were used for the first time in 1981. Each year, the seasonal adjustment is updated at the time the establishment series are adjusted to new benchmark levels, usually in July.

Additional research will be undertaken as part of the redesign to test various X-11 options for making better seasonal adjustments for industries that are periodically affected by strikes, product model changeover, holidays, and so forth. We will also try to determine whether the seasonal adjustment should be updated every 6 months rather than annually.

Data collection techniques. Because we know that our traditional method of solicitation and collection of data by mail does not provide sufficient sample representation in many of the service-producing industries, we will be experimenting with other means of obtaining employer cooperation and collecting monthly data. Our goal is to arrive at the least costly mix of mail, telephone, and personal visit to satisfy our sample design.

Estimation process. In recent years, research by David Birch of the Massachusetts Institute of Technology and others has indicated that it is the small, young, volatile service-producing firms that are responsible for nearly all of the net creation of new employment opportunities.[4] Unfortunately, these are the firms which are least likely to be adequately represented in the establishment survey as now designed. We plan to test additional size and regional stratification of our sample to improve our employment estimates for industries with large proportions of such firms; heretofore, extensions of the sample stratification system were generally intended to improve estimates of hours and earnings, rather than employment.

Hours and earnings estimation. Because of the changing mix of full- and part-time workers in many service-producing industries, coupled with problems in defining a "nonsupervisory worker," we plan to test several alternative hours and earnings measures. We hope to demonstrate an ability to collect an "all-employee" earnings measure that can be benchmarked annually to the wage data from the UI administrative data base. To obtain better and more meaningful hours measures, we will try to collect information separately for "permanent," versus "all other," employees. The relationship between hours worked and hours paid, which is especially important for the construction of the Bureau's productivity measures, will also be studied.[5]

IN VIEW OF BOTH the increasing importance of the service-producing sector and the shortcomings in the current statistical measurement system, improvement in the data for this sector takes on a very high priority in the Bureau's plans for survey modernization. Such improvement, however, constitutes a formidable challenge, given the preponderance of hard-to-measure smaller establishments and the attendant reporting difficulties.

The path to improvement is threefold: a fine-tuning of the data collection process to ease the response burden and extend coverage; a reconsideration of the sample design in order to better focus survey coverage; and a review and extension of procedures for generating estimates based on the survey responses. The initial research on improving data collection is complete, while development of sample design and estimating procedures continues. Over the next 3 years, as resources permit, the findings of the initial research will be evaluated and, if cost-effective, will be integrated into the survey operations. □

Unemployment and labor force trends in 10 industrial nations: an update

Postwar joblessness reaches 13 percent in Great Britain in the third quarter, with West Germany, France, Canada, and the United States also incurring record high unemployment rates

JOYANNA MOY

In the latter half of 1981 and the first 9 months of 1982, unemployment rates approximating U.S. concepts rose sharply in most of the 10 countries covered by the Bureau of Labor Statistics' series of comparative unemployment rates. Unemployment rates reached post-World War II highs in six of the industrial nations—the United States, Canada, France, West Germany, Great Britain, and the Netherlands. Italian unemployment, although at a comparatively moderate level of 4.7 percent after adjustment to U.S. concepts, was the highest since 1959. In addition, there were an equally large number of "discouraged workers" in Italy—persons who wanted jobs but had not actively sought work recently. Although Japanese and Swedish unemployment rates remained substantially lower, in the 2 to 3 percent range, both countries had higher rates than they normally experienced over the last 20 years. Australia was the only country where the jobless rate was down in 1981; it rose, however, in the first 9 months of 1982.

This article updates comparative unemployment rates through the third quarter 1982 and other related labor market statistics through 1981 for the 10 countries. The foreign unemployment and labor force data are adjusted to U.S. concepts. Some revisions of previously published estimates are also presented; the revisions arise from incorporation of more recent survey results.[1]

Unemployment pushes higher

In 1981, the U.S. unemployment rate of 7.6 percent was surpassed by the rates in Great Britain, 11.3 percent, the Netherlands, 8.9 percent, and France, 7.7 percent, and was matched in Canada. (See table 1.) The Australian rate fell to 5.8 percent. Unemployment rates of 4.2 percent were recorded in Germany and Italy; Japanese and Swedish jobless rates were in the 2 percent range.

By the second quarter of 1982, rates had risen in all 10 countries. The U.S. jobless rate, which had remained stable for the first three quarters of 1981, surged in the fourth quarter and reached new highs of 9.5 percent in the second quarter and 9.9 percent in the third quarter. Nevertheless, the U.S. rate was still exceeded by the rates in Great Britain, Canada, and probably the Netherlands.[2] The British rate, which rose to about 13 percent in early 1982, was the highest ever recorded in the BLS series of comparative unemployment statistics.

West Germany's unemployment rate also rose sharply in the fourth quarter of 1981 and the first half of 1982, while France and Italy experienced more moderate increases. However, both German and French third quarter rates were postwar records, and the second-

[1] Preliminary for West Germany from 1979 onward, and for France and Great Britain from 1981 onward.

[2] Quarterly data are for January, April, July, and October.

NOTE: Quarterly figures for France, West Germany, Italy, and Great Britain are calculated by applying annual adjustment factors to current published data and therefore should be viewed as only approximate indicators of unemployment under U.S. concepts. Published data for Australia, Canada, Japan, and Sweden require little or no adjustment.

quarter Italian rate was the highest in more than 20 years.

Japan's unemployment rate increased marginally to 2.4 percent in the second quarter, after remaining at about 2.2 percent for the previous three quarters. Sweden's unemployment rate rose from 2.2 percent in the first half of 1981 to 3.1 percent in the fourth quarter but remained at about 3.0 percent in the first half.

The current comparative unemployment situation is in marked contrast with the 1960's and early 1970's. In those years, unemployment rates in the United States and Canada were much higher than in Western Europe, Japan, and Australia. U.S. and Canadian rates averaged about 5 percent during that period, compared to 1 percent in Japan and Germany, 2 percent in Australia, France, and Sweden, and 3 percent in Great Britain and Italy.

Unemployment rates trended down in the second half of the 1960's in the United States, Canada, Japan, and Australia, while in the European countries they were up. In the early 1970's, unemployment rates were higher again in every country except Italy. In the United States, Canada, and Japan, however, they were still below the levels of the early 1960's. Subsequently, unemployment rates continued up in every country except Japan and Sweden.

Unemployment has risen more rapidly in most European countries and Australia than in the United States, Canada, and Japan since the 1973 oil embargo and the 1974–75 recession. By the early 1980's, West Germany's unemployment rate was more than 6 times as high as in 1960–74. French jobless rates increased more than fourfold by 1980–82, British rates more than tripled and Australian rates tripled. In the United States and Canada, 1980–82 unemployment rates were about 50 percent higher than in 1960–74. However, both countries had begun with relatively high rates in the earlier period. Japan's unemployment rate increased somewhat more, but remained well below 3 percent. The smallest increases in unemployment rates since 1960–74 occurred in Sweden and Italy. Italy's rates were the highest in Europe during the earlier period, however, and its recent rates exclude a large group of discouraged workers. Sweden, by contrast, now has the lowest unemployment rate among the European countries.

Employment shows broad decline

In the first half of 1982, employment rose over 1981 in only 2 of the 10 countries studied—by 0.6 percent in Japan and by 0.2 percent in Australia. Employment declined most sharply in Canada, 1.9 percent, and Great Britain, 1.7 percent. Employment fell by 1 percent or less in the United States, West Germany, Italy, and Sweden and probably in France and the Netherlands as well.

In 1981, employment had increased about 1 percent in the United States and Japan and 2 to 2.5 percent in Australia and Canada. Among the European countries, employment increased only in Italy, a marginal 0.5 percent; in the other countries, employment declined. The largest decline was 4 percent in Great Britain. (See table 2.)

Employment growth was stronger in North America, Australia, and Japan than in Western Europe in earlier periods also. For all six European countries, annual average employment growth had been only 1 percent or less since 1960. In the 1960–73 period, the employment trend was negative only in one country, Italy; since 1973, the overall employment trend had been down in West Germany and Great Britain.

Employment maintenance programs. Special employment maintenance and training programs have had a significant impact on the 1981–82 employment levels in several European countries. For example, in June 1982, about 535,000 Britons were covered by various employment and training schemes. According to the British Department of Employment, the direct effect of these programs was to keep about 300,000 persons (1.1 percent of the labor force) off the June 1982 unemployment register.[3] In Sweden, although the number in training programs for labor market reasons declined in 1981, the total enrolled in the various public works and training programs actually exceeded the number of unemployed by 8 percent and accounted for 2.7 percent of the labor force (versus an unemployment rate of 2.5 percent).

In France, West Germany, Great Britain, and Italy, employment was supported by wide-reaching programs to subsidize employees placed on shorter hours for economic reasons. In France, an average of nearly 320,000 workers, equivalent to approximately 14.3 million work days, were covered in the first 10 months of 1981. The number of workers covered, 1.4 percent of the labor force, was up 130 percent from the first 10 months of 1980. In West Germany, the number of persons on short-time increased 150 percent in 1981 to nearly 350,000 workers, about 1.3 percent of the labor force. In Great Britain, the number covered by the Temporary Short-Term Working Compensation Scheme in 1981 ranged from a high of nearly one million in March to 190,000 in December. The average for the year, about 540,000, was 2.2 percent of the labor force. In the first half of 1982, the number receiving benefits declined further, to under 150,000 persons. In Italy, the number of hours subsidized by the Wage Supplement Fund rose 85 percent to 550 million hours in 1981. If the number of hours subsidized were spread among all employed persons, then approximately 27 hours per person were subsidized in 1981; or, assuming 1,800 hours worked per person, the equivalent of 1.4 percent of the labor force was subsidized.

Employment-population ratios. Although employment rose in 1981 in five of the countries, the employment-population ratio rose only in Canada. In the other four countries—the United States, Japan, Australia, and Italy—employment growth matched growth in the working age population, and employment ratios were virtually unchanged. The employment ratio fell sharply from 1980 in Great Britain, along with the 1-million decline in employment. Employment-population ratios also fell in France, West Germany, the Netherlands, and Sweden. (See table 2.) Sweden still had by far the highest employment ratio, 65 percent. By comparison, the 1981 ratios were around 60 percent in the United States, Canada, Japan, and Australia; 50 to 55 percent in France, West Germany, and Great Britain; and about 45 percent in the Netherlands and Italy.[4]

Labor force participation stable

With the exceptions of Canada and Great Britain, there was little or no change in 1981 in labor force participation rates—the proportion of the civilian working-age population in the labor force. In Canada, the participation rate rose to 64.7 percent in 1981 from 64.0 percent in 1980, the increase resulting entirely from continued growth in the female participation rate. In Great Britain, by contrast, the overall participation rate declined for the third consecutive year as both male and female participation continued to move downward. In most countries, changes in participation were characterized by secular downtrends for men and increases for women.

Labor force participation rates continued to be highest in Sweden, 67 percent, and lowest in Italy, 48 percent. In West Germany and the Netherlands, slightly more than 50 percent of the working age population were employed or looked for work in 1981, compared to 57 percent in France and 62 to 65 percent in the other five countries. (See table 2.)

Discouraged workers. Data on discouraged workers—persons who state a current desire for work but who are not actively seeking a job because they think they cannot find one—are available only for the United States, Canada, Sweden, and Italy. In the United States, the number of discouraged workers doubled from 1979 to 1.5 million (compared with around 10 million unemployed persons). The Canadian definition of discouraged workers is somewhat more restrictive than the U.S. definition.[5] Nevertheless, the number of discouraged workers, as in the United States, is currently equivalent to about 15 percent of the unemployed. In Sweden, the number of discouraged workers had been about half the number of unemployed since 1978.

In Italy, the number of persons not in the labor force who were classified, by Italian definitions, as discouraged jobseekers in 1981 was only about 80,000—equivalent to less than 10 percent of the number unemployed. In addition, however, approximately half the Italians who stated they were unemployed said they had not actively sought work within the last 30 days. These persons have been excluded from the unemployed by BLS, because U.S. concepts require active workseeking

[1] Preliminary estimate based on incomplete data.

[2] Civilian labor force as a percent of civilian working age population.

[3] Civilian employment as a percent of civilian working age population.

[4] Published and adjusted data for the United States, Canada, and Australia are identical. For France, unemployment as a percent of the civilian labor force; for Japan, Italy, and Sweden, unemployment as a percent of the civilian labor force plus career military personnel; for West Germany, Great Britain, and the Netherlands, registered unemployed as a percent of employed wage and salary workers plus the unemployed. With the exception of France, which does not publish an unemployment rate, these are the usually published unemployment rates for each country.

[5] Italian Central Institute of Statistics estimate made for comparability with the revised labor force survey, introduced in 1977.

NOTE: Data for the United States relate to the population 16 years of age and over. Published data for France, West Germany, Italy, and the Netherlands relate to the population 14 years of age and over; for Sweden, to the population aged 16 to 74; and for Canada, Australia, and Japan, to the population 15 years of age and over. For Great Britain, the lower age limit was raised from 15 to 16 in 1973. The statistics have been adapted, insofar as possible, to the age at which compulsory schooling ends in each country. Therefore, the adjusted statistics for France relate to the population 16 and over and for West Germany and the Netherlands, to the population 15 years of age and over. The age limits of the statistics for Canada, Australia, Japan, Great Britain, and Italy coincide with the age limits of the published statistics. Statistics for Sweden remain at the lower age limit of 16, but have been adjusted to include persons 75 years of age and over.

in the last 4 weeks (unless on temporary layoff or waiting to begin a new job). Under U.S. concepts, however, many of these persons would be classified as discouraged workers.

Foreign worker joblessness high

Foreign workers continue to be an important factor in the unemployment rates in Western Europe, particularly in West Germany, France, and Sweden. In 1981, foreign workers made up 9.2 percent of the labor force in West Germany, 6.3 percent in France, and 5.4 percent in Sweden; and in all three countries, foreign nationals had substantially higher unemployment rates than native-born workers.

In France, the foreign worker unemployment rate was nearly twice the overall rate in March 1981. Unemployment among both foreign workers and the native born increased at similar rates from 1980. In West Germany, the foreign worker unemployment rate had been increasing more rapidly than the overall rate. In the first quarter of 1982, the rate for foreigners was 50 percent higher than the overall jobless rate; in 1980, it was about one-third higher. Jobless rates for migrant workers in Sweden had been about double the overall rates since the labor force survey began collecting the data in 1977. In the first quarter of 1982, the foreign worker rate reached 6 percent, while the overall rate rose to 3 percent.

FOOTNOTES

[1] For further information, see *International Comparisons of Unemployment*, Bulletin 1979, Appendix B (Bureau of Labor Statistics, 1978); and Supplement to Bulletin 1979, Appendix B (Bureau of Labor Statistics, 1982).

[2] Seasonally adjusted quarterly unemployment rates approximating U.S. concepts are not available for the Netherlands. However, the seasonally adjusted registered unemployment rate for the first quarter of 1982 indicates that the Dutch unemployment rate approximating U.S. concepts would probably be higher than the first-quarter U.S. rate.

[3] Department of Employment, "Special Employment and Training Measures," Press Notice, July 20, 1982, p. 1.

[4] In Italy, the employment ratio is understated because of the large pool of "black labor"—persons with an unreported job and whose labor force status is reported as unemployed or not in the labor force. For further information, see *International Comparisons of Unemployment*, p. 134.

[5] In Canada, discouraged workers must have actively sought work within the last 6 months. In the United States, recent jobseeking is not required in order to be classified as discouraged.

A new look at occupational wages within individual establishments

Analysis of wage structures shows that pay differences within individual establishments are generally smaller than those of the surveywide average

ROBERT W. VAN GIEZEN

Reports containing results of occupational wage surveys generally emphasize average earnings of individual jobs. While these types of data are useful to those interested in levels of pay and overall relationships among occupational averages, they do not show occupational pay differentials within individual establishments. For example, according to a Bureau of Labor Statistics report on pay levels in metropolitan areas, janitors averaged $4.87 an hour in July 1980 and tractor-trailer truckdrivers averaged $9.63, or nearly twice as much.[1] But, the average pay differential within individual establishments having both janitors and tractor-trailer drivers was only about 30 percent.

Data on internal pay alignments are of special concern to wage and salary administrators, labor-management contract negotiators, and those who develop or analyze internal wage structures. Although not necessarily to the degree indicated by the comparison of janitors and truckdrivers, pay setters may find a conflict between the twin objectives of gearing occupational pay rates to local labor market conditions and, at the same time, maintaining appropriate internal pay structures. Reconciliation of these conflicting objectives can be a major issue in wage and salary administration.[2] To satisfy the need for information on internal pay alignments, the Bureau of Labor Statistics now reports average occupational pay relationships within establishments in its *Area Wage Survey* publications.[3] This article presents an analysis of pay relatives for all metropolitan areas combined, and summarizes the within establishment differences among industry divisions, regions, and establishment size groups.[4]

Method an analysis

A simple numerical example may sharpen the distinction between the two approaches to analyzing occupational wage relationships. The following tabulation uses hypothetical data to illustrate pay relationships of surveywide averages versus those within establishments:

	Establishment			*All establishments*
	A	*B*	*C*	
Surveywide:				
Job 1				
Number of workers . . .	5	1	3	9
Hourly pay	$4	$7	$6	$5
Job 2				
Number of workers . . .	1	2	–	3
Hourly pay	$5	$11	–	$9
Within establishments:				
Number of workers . . .	6	3	–	9
Pay relative	125	157	–	136

The traditional approach—comparison of published survey averages for individual jobs—is influenced by the numbers of workers in these jobs in establishments having different pay levels, as well as by differences in occupational pay levels. Using this approach, the survey average pay in all establishments for job 2 ($9) exceeds that for job 1 ($5) by 80 percent. However, when

---

Robert W. Van Giezen is a labor economist in the Division of Occupational Pay and Employee Benefit Levels, Bureau of Labor Statistics. Barbara L. Spector of the Office of Statistical Operations provided valuable statistical assistance.

the focus shifts to the pay differentials *within* individual establishments, a 36-percent differential results. The differential is computed by averaging pay relatives (average earnings for job 2 as a percent of earnings for job 1) of all establishments, using combined employments of the two jobs as weights. The difference between within establishment and surveywide relationships is affected if an establishment has only one of the two jobs being compared. (Note that establishment C with only one of the jobs is not used in the computation.)

In this tabulation, the average pay difference within establishments (*intra-establishment* differential) is less than the difference between the survey averages for the two jobs (*inter-establishment* differential). However, this is not always the case. The inter-establishment differential would be smaller than the intra-establishment differential if a high-paying firm had a concentration of workers in a low-paying job, or if a low-paying firm had a concentration of workers in a high-paying job.

Intra- versus inter-establishment relationships

Both intra- and inter-establishment pay relationships are shown in table 1. These comprehensive matrices show average pay relationships between pairs of jobs. For example, reading across the row for tractor-trailer drivers, the pay relative of 129 in the janitors column means that the average pay advantage of the drivers over janitors in establishments with both these occupations was 29 percent. The figure in parenthesis, 198, means that the survey average for tractor-trailer drivers in all metropolitan areas was almost double that of janitors when data from all establishments (having either one or both of the jobs) were used in the calculation. Similarly, the data show intra- and inter-establishment pay advantages of tractor-trailer drivers over class B guards of 31 and 132 percent, respectively.[5] These differences between intra- and inter-establishment pay relatives are extreme cases. The comparisons were much closer for most occupational pairings.

A seeming inconsistency in the relationships among some occupations must be explained. For example, intra-establishment differences show a pay advantage of 5 percent for tractor-trailer drivers and of 7 percent for drivers of heavy trucks, when drivers of light trucks serve as a base. One might conclude that within individual establishments, drivers of heavy trucks earn more than drivers of tractor-trailers. However, direct comparisons between these two jobs show a 1-percent advantage in favor of tractor-trailer drivers. The incongruity is eliminated when it is recognized that establishments employing light-truck and tractor-trailer drivers are not necessarily the ones that employ both light- and heavy-truck drivers or both tractor-trailer and heavy-truck drivers. Each comparison is based on a different set of observations.

Intra-establishment differentials were generally smaller, and substantially so in a number of instances, than inter-establishment differences for the same occupations. This is revealed most strikingly in the comparisons between material movement and custodial occupations, where 90 percent of the inter-establishment differentials exceeded intra-establishment differences. For example, overall survey averages show that material handling laborers earned 71 percent more than class B guards, while the average intra-establishment advantage for these laborers was only 4 percent. These findings can be related to the industrial incidence of the two jobs: many material handling laborers are employed in highly paid and heavily unionized industries; conversely, many guards are employed by protection agencies paying near the Federal minimum wage. This employment pattern tends to widen the difference between surveywide averages but has no effect on occupational pay differentials within individual establishments.

Similar findings appear when the analysis is limited to various levels or classifications of the same occupation. Based on inter-establishment comparisons, drivers of tractor-trailer trucks averaged more than drivers of other trucks, up to 50 percent more than drivers of light trucks. However, when the earnings of truckdrivers within the same establishment are compared, the average differential is lowered to a maximum of 5 percent.

Occupational earnings differentials—whether measured by inter- or intra-establishment differentials—were lower among maintenance, toolroom, and powerplant jobs than any other occupational group studied. The relative homogeneity among these occupations can be explained by several factors. First, almost all of the jobs studied were at the journeyman level of skill, and the workers often were under single-rate pay systems. Second, more than 80 percent of the workers were employed in a single industry division—manufacturing. Finally, these occupations are among the most heavily unionized of the occupations studied. As will be shown later, the findings of this study generally are consistent with the idea that inter-occupational wage differentials are narrower in the union sector.

Except for higher paid tool-and-die makers and lower paid boiler tenders and maintenance helpers, pay rates within establishments were almost identical for all the maintenance, toolroom, and powerplant jobs. Nevertheless, overall survey averages were not reliable indicators of intra-establishment relationships. For example, the overall average pay of millwrights was 4 percent above that for tool-and-die makers, while the intra-establishment pay relationship was reversed—millwrights averaged 4 percent less than tool-and-die makers. This type

Table 1. Intra- and inter-establishment pay relationships between occupations, all metropolitan areas, July 1980

[Inter-establishment pay relative in parenthesis]

Occupations for which earnings are compared	Occupations for which average earnings equals 100								
	Truckdrivers				Power-truck operators (other than forklift)	Forklift operators	Receivers	Shippers and receivers	Warehouse workers
	Tractor-trailer	Heavy truck	Medium truck	Light truck					
Material movement and custodial									
Truckdrivers, tractor-trailer	100	101 (118)	102 (115)	105 (156)	106 (127)	108 (124)	108 (144)	109 (147)	109 (135)
Truckdrivers, heavy truck	99 (86)	100	106 (100)	107 (135)	106 (110)	107 (107)	114 (124)	111 (127)	111 (117)
Truckdrivers, medium truck	98 (87)	94 (100)	100	106 (135)	102 (110)	105 (107)	103 (125)	104 (128)	105 (117)
Truckdrivers, light truck	95 (64)	94 (74)	95 (74)	100	98 (81)	102 (79)	97 (92)	98 (94)	103 (87)
Power-truck operators (other than forklift)	94 (79)	94 (91)	98 (81)	102 (123)	100	100 (97)	99 (113)	102 (116)	102 (107)
Forklift operators	93 (81)	93 (94)	96 (93)	98 (128)	100 (109)	100	99 (116)	99 (119)	100 (109)
Receivers	92 (69)	88 (81)	97 (80)	104 (108)	101 (88)	101 (86)	100	96 (102)	102 (94)
Shippers and receivers	92 (68)	90 (79)	96 (79)	102 (108)	98 (88)	101 (84)	104 (98)	100	102 (92)
Warehouse workers	92 (74)	90 (86)	95 (85)	97 (115)	98 (94)	100 (91)	98 (108)	98 (109)	100
Shippers	91 (70)	90 (81)	99 (81)	105 (110)	103 (88)	103 (87)	101 (101)	101 (104)	134 (95)
Material handling laborers	91 (74)	90 (85)	90 (85)	91 (115)	97 (94)	96 (91)	92 (108)	94 (109)	92 (100)
Order fillers	90 (66)	86 (79)	92 (79)	96 (107)	99 (87)	97 (85)	93 (99)	96 (101)	96 (93)
Guards, class A	84 (63)	92 (73)	87 (72)	98 (98)	96 (80)	96 (78)	98 (90)	101 (92)	94 (85)
Shipping packers	84 (61)	71 (71)	84 (70)	91 (86)	97 (77)	96 (75)	90 (88)	92 (90)	94 (82)
Janitors, porters, and cleaners	77 (51)	72 (58)	78 (56)	82 (79)	92 (64)	90 (63)	86 (73)	86 (75)	84 (69)
Guards, class B	76 (43)	65 (50)	75 (50)	92 (67)	93 (56)	94 (53)	91 (62)	93 (64)	89 (58)

Occupations for which earnings are compared	Tool-and-die makers	Maintenance electricians	Maintenance machinists	Stationary engineers	Maintenance mechanics (machinery)	Maintenance sheet-metal workers	Maintenance pipefitters	Maintenance mechanics (motor vehicles)
Maintenance, toolroom, and powerplant								
Tool-and-die makers	100	103 (102)	104 (108)	104 (110)	105 (109)	104 (97)	104 (98)	104 (106)
Maintenance electricians	97 (98)	100	100 (104)	101 (108)	101 (107)	101 (96)	102 (97)	103 (105)
Maintenance machinists	96 (95)	100 (96)	100	102 (104)	102 (103)	101 (92)	102 (93)	103 (101)
Stationary engineers	96 (91)	99 (93)	98 (96)	100	100 (99)	100 (89)	101 (89)	101 (97)
Maintenance mechanics (machinery)	96 (92)	96 (94)	98 (97)	100 (101)	100	100 (90)	101 (91)	101 (98)
Maintenance sheet-metal workers	96 (103)	99 (105)	99 (109)	100 (113)	100 (112)	100	100 (101)	100 (109)
Maintenance pipefitters	96 (102)	98 (103)	99 (108)	99 (112)	99 (110)	100 (98)	100	100 (108)
Maintenance mechanics (motor vehicles)	96 (94)	97 (95)	97 (99)	99 (103)	99 (102)	100 (91)	100 (92)	100
Millwrights	95 (104)	98 (106)	97 (110)	99 (114)	99 (113)	100 (101)	100 (102)	100 (111)
Machine-tool operators (toolroom)	95 (98)	98 (100)	97 (104)	100 (108)	99 (107)	101 (96)	100 (97)	101 (105)
Maintenance carpenters	94 (90)	97 (92)	97 (96)	98 (99)	98 (98)	99 (88)	99 (89)	100 (96)
Maintenance painters	93 (87)	94 (88)	94 (92)	96 (96)	94 (94)	97 (85)	97 (85)	97 (93)
Boiler tenders	90 (79)	92 (83)	91 (83)	90 (86)	93 (85)	94 (77)	95 (77)	95 (84)
Maintenance trades helpers	77 (75)	80 (76)	82 (79)	83 (82)	82 (81)	84 (73)	85 (73)	82 (79)

Occupations for which earnings are compared	Computer systems analysts (business)			Computer programmers (business)			Computer operators		
	Class A	Class B	Class C	Class A	Class B	Class C	Class A	Class B	Class C
Professional and technical									
Computer systems analysts, class A	100	119 (116)	141 (134)	129 (124)	149 (147)	175 (177)	162 (161)	190 (196)	220 (227)
Computer systems analysts, class B	84 (86)	100	120 (116)	111 (107)	129 (127)	149 (153)	137 (139)	161 (169)	188 (196)
Computer systems analysts, class C	71 (75)	84 (86)	100	94 (92)	112 (108)	128 (132)	117 (120)	136 (146)	156 (170)

NOTE: See page 23 for a description of these pay relationships and method of computation.

of leadership reversal occurred in about a fifth of the observations.

Inter-establishment pay differences for the professional and technical group also were often poor indicators of intra-establishment pay differentials. Although a tenth of the comparisons between these two measures yielded identical results, differences were 10 points or more in almost a fourth of the observations.

The office clerical group—with five classes of secretaries, three classes of file clerks, and two classes each of stenographers, typists, order clerks, and key entry operators—provides an opportunity to examine wage relationships among workers in the same occupation, but with differing amounts of responsibility. For example, the five classes of secretaries are defined according to the secretary's responsibility and supervisor's position in the organization.[6] Within establishments, each level of secretary provided an average pay gain of from 13 to 17 percent; consequently, the highest level—secretary to board chairman or company president of a medium size firm—averaged 53 percent more than the lowest level—a secretary to a staff specialist or supervisor of a small unit.

In all of the comparisons among the secretaries, pay differentials within establishments exceeded those between surveywide averages. This relationship was also found among other occupations, mainly in the white-collar field. Intra-establishment differences were larger than inter-establishment differences in about two-fifths of the professional-technical and a fourth of the office clerical comparisons. In contrast, this pattern occurred in only 8 percent of both the material movement-custodial and maintenance-toolroom-powerplant comparisons.

As noted, average occupational pay differentials within establishments will exceed those between published averages where high-paying firms have a disproportionately large number of employees in less skilled jobs reported for the survey, or where low-paying firms have a disproportionately large number of employees in more skilled jobs. These conditions may be more common among white-collar jobs, which are spread across industries with differing pay levels.[7]

Differences by sector

Intra-establishment pay relationships differed among the industry divisions, regions, and establishment size groups studied separately. Within establishments, pay differentials between jobs were narrower in manufacturing, the North Central region, and large establishments, and were broader in nonmanufacturing, the South, and small establishments. (These findings, of course, are interrelated.)

To summarize these relationships, intra-establishment relatives were calculated for each industry, region, and establishment size group studied. The absolute difference for each occupational comparison was computed by subtracting the pay relative from 100. Ignoring the sign of the remainder, these differences were totaled and divided by the number of comparisons to find an average difference.[8] Therefore, a small average difference in table 2 indicates a narrow wage structure and a large difference indicates a broad wage structure.

Professional-technical and office clerical jobs had the highest average differences, 29 and 19 points, respectively. The average difference for maintenance, toolroom, and powerplant occupations was 5 points, and for material movement and custodial jobs, 8 points. These results are not surprising, considering the wide range of skill levels in the white-collar field. For example, professional and technical jobs ranged from highly skilled systems analysts responsible for complex problems to entry-level computer operators. These skill distinctions were not as pronounced among the blue-collar occupations.

Differences in occupational pay relationships were small but consistent among the industries, regions, and size-of-establishment groupings studied. These differ-

ences were larger in nonmanufacturing than manufacturing industries for three of the occupational groups. (Because of insufficient data for nonmanufacturing industries, such a comparison could not be made for maintenance, toolroom, and powerplant jobs.)

Regional differences in occupational wage structures were relatively minor, as were the differences by size of establishment.[9] Nevertheless, the South had the largest differentials for 2 of the 4 occupational groups, and tied for the largest for a third group.[10] Among the other three regions, the North Central area had the smallest occupational wage differentials for the two blue-collar groups and for office clerical workers. Occupational pay differences in large establishments, on average, were smaller for all occupational groups, except office clerical jobs—where no size-of-establishment variation was found.

Table 2. Average intra-establishment pay differences among occupations, by selected characteristics, July 1980

[In percentage points]

Characteristics	Material movement and custodial	Maintenance, toolroom, and powerplant	Professional and technical	Office clerical
All establishments	8	5	29	19
Industry:				
Manufacturing	7	5	26	17
Nonmanufacturing	11	([1])	32	20
Region:				
Northeast	9	6	31	20
South	9	7	32	20
North Central	8	5	26	18
West	10	6	29	19
Establishment size:				
Fewer than 1,000 workers	10	6	34	19
1,000 workers or more	7	5	27	19

[1] Data do not meet publication criteria.

NOTE: See page 25 for explanation of method of computation and footnote 4 of text fur definitions of industry divisions and regions.

Although the impact of unionization on wage structures could not be directly examined in this study, the data suggest the possibility that internal occupational pay differentials are smaller where labor-management agreements are in effect. Manufacturing, non-Southern regions, and large establishments generally had both smaller pay differences and a higher concentration of workers under labor-management agreements than did nonmanufacturing, the South, and small establishments. An earlier study of production worker earnings in 49 manufacturing and 6 mining industries also showed lower dispersion rates among highly unionized industries.[11] This earlier study, however, used the more traditional analysis of union impact by focusing on inter-establishment variations.[12]

Cost-of-living adjustment clauses found in many union contracts may contribute to a lower wage dispersion in the union sector.[13] These clauses provide for periodic wage adjustments in keeping with changes in a designated price index, such as the Bureau's Consumer Price Index. They usually call for uniform cents-per-hour wage adjustments to all covered employees, and thus tend to reduce percentage differences among occupational wages. ☐

[1] See *Occupational Earnings in All Metropolitan Areas, July 1980*, Summary 81-11 (Bureau of Labor Statistics, 1981), p. 3.

[2] See E. Robert Livernash, "The Internal Wage Structure," in George W. Taylor and Frank C. Pierson, eds., *New Concepts in Wage Determination* (New York, McGraw-Hill Book Co., 1957), pp. 155–58.

[3] See, for example, tables A-8 to A-11 of *Area Wage Survey: Chicago, Ill., Metropolitan Area, March 1982*, Bulletin 3015-9.

[4] All data in this article refer to the 262 Standard Metropolitan Statistical Areas of the United States (excluding Alaska and Hawaii), as defined by the Office of Management and Budget through February 1974. BLS surveys are conducted annually in a sample of 70 areas se-

lected and appropriately weighted to represent all 262 areas. Establishments employing 50 workers or more are surveyed in six broad industry divisions: manufacturing; transportation, communication, and other public utilities; wholesale trade; retail trade; finance, insurance, and real estate; and selected services. In the 13 largest areas, the minimum etablishment size is 100 workers in manufacturing; transportation, communication, and other public utilities; and retail trade. Major exclusions from the survey are construction, extractive industries, and government. The regions are defined as follows: *Northeast*—Connecticut, Maine, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, and Vermont; *South*—Alabama, Arkansas, Delaware, District of Columbia, Florida, Georgia, Kentucky, Louisiana, Maryland, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia, and West Virginia; *North Central*—Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin; and *West*—Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, and Wyoming.

[5] Intra-establishment pay relationships were computed using the following procedures: (1) establishments employing workers in both of the paired occupations were identified; (2) establishment pay levels (averages) for the two occupations were weighted by the combined employment of both jobs to reflect each establishment's contribution to the totals used in the comparison; (3) the weighted pay levels of the two jobs were summed separately across establishments; and (4) each total was divided by the other and the quotients multiplied by 100 to produce the two intra-establishment pay relatives shown for each job pairing.

[6] Job descriptions for the occupations included in area wage surveys are available from the Bureau's regional offices listed on the front cover.

[7] An earlier Bureau study—which compared all occupations surveyed to janitors—had similar findings. In many cases, pay differences between white-collar jobs and janitors were larger when measured within establishments than when overall averages were compared. On the other hand, in almost all blue-collar comparisons, intra-establishment differentials were smaller than those between survey averages. See Virginia L. Ward, "Measuring wage relationships among selected occupations," *Monthly Labor Review*, May 1980, pp. 21–25.

[8] For a further discussion of this technique, see Mark S. Sieling, "Interpreting pay structures through matrix application," *Monthly Labor Review*, November 1979, pp. 41–45.

[9] Regional patterns are composites of numerous individual areas, each with a distinct industrial and occupational pattern. For local pay setting purposes, data similar to those in table 1 are published annually for 70 areas in individual area wage survey bulletins.

[10] This confirms an earlier conclusion of H. M. Douty that "Wage differentials based on skill level tend to be greater within the South than in the remainder of the country. . ." See H. M. Douty, "Wage Differentials: Forces and Counter Forces," *Monthly Labor Review*, March 1968, p. 76.

[11] Carl B. Barsky and Martin E. Personick, "Measuring wage dispersion: pay ranges reflect industry traits," *Monthly Labor Review*, April 1981, pp. 35–41.

[12] Unionism, of course, is only one of a number of influences on occupational wage differentials. Its impact is by no means a settled issue. For a sample of the literature on this subject, see Clark Kerr, "Wage Relationships—The Comparative Impact of Market and Power Forces," in John T. Dunlop, ed., *The Theory of Wage Determination* (New York, St. Martin's Press, 1957), pp. 173–93; Lloyd G. Reynolds and Cynthia H. Taft, *The Evolution of Wage Structure* (New Haven, Yale University Press, 1956); Sherwin Rosen, "Unionism and the Occupational Wage Structure in the United States," *International Economic Review*, June 1970, pp. 269–86; and Robert N. Schoeplein, "Secular Changes in the Skill Differential in Manufacturing, 1952–1973," *Industrial and Labor Relations Review*, April 1977, pp. 314–24.

[13] Cost-of-living adjustment clauses cover more than half of the workers under major collective bargaining agreements. See Edward Wasilewski, "Scheduled wage increases and cost-of-living provisions in 1980," *Monthly Labor Review*, January 1980, p. 10.

Import price indexes for crude petroleum

On the basis of data reported by firms to the U.S. Department of Energy, BLS has developed measures of monthly price change for oil imports

EDWARD E. MURPHY AND MARK MCENEARNEY

The Bureau of Labor Statistics' International Price Program is responsible for calculating import and export price indexes for the United States. These indexes are statistical measures of the average change in prices of commodities that are traded between the United States and the rest of the world.

The program was originally funded by Congress in 1970. Price indexes were first published for exports in 1971, and for imports, in 1973. As of June 1982, published indexes accounted for 71 percent of the value of exports and 96 percent of the value of imports. Plans for the program include provisions for increasing the share of exports and imports for which indexes are calculated to 100 percent.

This article describes the International Price Program's price index for crude petroleum imports. The index, which was first published in November 1981,[1] is calculated using price and quantity data collected by the U.S. Department of Energy.

The data in table 1 show how important crude petroleum imports have become to the U.S. economy. In 1970, the United States imported 545 million barrels of crude petroleum at a cost of $1.3 billion. These imports accounted for 13.4 percent of the total U.S. supply of crude petroleum (imports plus domestic production) and 3.2 percent of total merchandise imports. In 1981, U.S. imports of crude petroleum, which measured 1,763 million barrels and cost $61.9 billion, accounted for 36.1 percent of the total U.S. supply of crude petroleum and 23.7 percent of total merchandise imports.

The following discussion is divided into sections that focus on different aspects of calculating and publishing the index. These include: (1) the construction of the index; (2) the specification of items in the index market basket; (3) the prices and weights that are used to compute the index; (4) the sources of the data; (5) the results of index calculations for the months January 1976 to May 1982; and (6) the policy for revising previously published index values.

Construction of the index. The price index for U.S. imports of crude petroleum is a Laspeyres fixed baseweighted index. The index may be interpreted as a measure of the change in the cost of buying the index market basket, or as a measure of the average change in the prices of items in the index market basket. For this index, the market basket consists of the various crudes—

Table. 1. U.S. imports of crude petroleum, 1970–81

Year	Crude imports (millions of barrels)	Crude imports (billions of dollars)	Crude imports as a percent of total U.S. supply	Crude imports as a percent of total imports
1970	545	1.3	13.4	3.2
1971	676	1.7	16.4	3.7
1972	901	2.4	20.7	4.3
1973	1,294	4.2	27.8	6.1
1974	1,367	15.3	29.9	15.3
1975	1,585	18.4	34.1	19.1
1976	2,050	25.5	40.8	21.1
1977	2,520	33.6	45.6	22.9
1978	2,392	32.1	42.9	18.7
1979	2,467	46.1	44.1	22.3
1980	1,977	62.0	38.6	25.7
1981	1,763	61.9	36.1	23.7

SOURCE: Bureau of the Census, *U.S. General Imports*, FT135, and U.S. Department of Energy, *1981 Annual Report to Congress.*

Edward E. Murphy is chief of the Division of International Price Indexes, Bureau of Labor Statistics. Mark McEnearney is an economist in the same division.

for example, Saudi Arabian Light, Mexican Isthmus, and Nigerian Bonny Light—that refiners and other buyers imported into the United States in 1980. A simplified version of the formula for computing the index is:

$$(1)\ I^t = \frac{\Sigma_{ij} P^t_{ij} \times Q^0_{ij}}{\Sigma_{ij} P^0_{ij} \times Q^0_{ij}} \times 100$$

$$(2) = \frac{\Sigma_{ij} W_{ij} \times P_{ij}{}^t / P_{ij}{}^0}{\Sigma_{ij} W_{ij}} \text{sf,10} \times 100$$

$$\text{for } W_{ij} = P^0_{ij} \times Q^0_{ij}$$

where:

I^t = the index in month *t*;

P^0_{ij} = the price, in dollars per barrel, that company *i* paid for shipments of crude type *j* imported in month *0* (the base period);

P^t_{ij} = the price, in dollars per barrel, that company *i* paid for shipments of crude type *j* imported in month *t* (the comparison period);

Q^0_{ij} = the quantity, in barrels, of crude type *j* that company *i* imported in month *0* (the base period);

W_{ij} = the dollar value weight assigned to crude type *j* imported by company *i*.

Specification of items in the market basket. Price indexes of the Laspeyres type are designed to measure changes in the cost of a given market basket (as opposed of differences in the cost of different market baskets). In the calculations for the crude petroleum index, this is accomplished by ensuring that the items that correspond to the prices in the numerator and denominator of each term in expression (2) above have identical specifications in all months.

The specification of each item in the market basket consists of two pieces of information. These are (1) a crude stream identifier, which shows where the crude in each import shipment was produced (the crude stream accounts for the essential quality characteristics of each crude, such as specific gravity, pour point, sulfur content, and trace element content); and (2) an identifier for the purchasing party. The inclusion of these two pieces of information in the specification ensures that when prices are compared over time they are compared for identically specified items.

Prices. The prices used to compute the index are the amounts, in dollars per barrel, that importing companies pay for their crude, plus any charges incurred in placing the crude on board ship at the foreign port of loading. Prices do not include any of the costs involved in transporting crude from the foreign port to the U.S. port of entry.

Weights. The weight assigned to each item in the market basket is the dollar value of all shipments of that item that were imported into the United States in 1980. In the process of computing the index for the current month, the weights are normalized to account for items in the market basket that were not imported. This is equivalent to imputing a price change equal to the weighted average price change of all items that were imported in the current month, as measured by the change in the index, to items that were not imported in the current month.

Data sources. The data used to compute the index are collected by the U.S. Department of Energy on the monthly Transfer Pricing Report (Form ERA-51, Schedule B). Reporting firms are major importers (those that import 500,000 or more barrels of crude in a given month) and firms that acquire imported crude from affiliated entities. About 40 firms file the report on a regular basis. In 1980, the data in the reports filed by these firms accounted for approximately 90 percent, in dollar terms, of all U.S. imports of crude petroleum.

Firms have 45 days after the end of a given month to file their reports with the Department of Energy. At the Energy Department, data from the reports are keypunched and screened for simple arithmetic errors and errors in transcription. In cases involving apparent errors in the data that cannot be resolved on the basis of the available information, the Department contacts the reporting firm to verify the data that have been reported and, if necessary, obtains the correct information.

Approximately 60 days after the end of a given month, the Department of Energy provides BLS with a computer tape containing these data. At BLS, the data are screened again. Any questions that arise with respect to the data are referred to the Department of Energy and resolved before the data are used to compute the index. The processing associated with computing the index is generally complete within 10 days of receipt of the tape from the Energy Department.

Index values, January 1976 to May 1982. Table 2 shows index values that have been calculated for 11 categories of crude petroleum imports. These include imports from all countries, from members of the Organization of Petroleum Exporting Countries (OPEC)[2] and from nonmembers, and from selected regions and countries. The number of regions and individual countries for which index values are shown is limited by the availability of price data. In keeping with BLS standards for maintaining the confidentiality of company level data, index values that were calculated with prices from fewer than three companies are not shown.

As measured by the index for imports from all countries, prices of imported crude petroleum have nearly tripled since January 1976, the first month for

which the index was calculated. Prices increased slowly during 1976 and 1977, rising a total of 11 percent over the 24-month period. In 1978, a quiet year in the world petroleum market, prices were virtually unchanged, but between January 1979 and January 1980, the index rose 100 points, from 105.5 to 205.8. During the latter year, political events seriously disrupted the flow of petroleum exports from Iran, at one time the leading oil producing country in OPEC after Saudi Arabia. Prices continued to rise in 1980 and in the first 2 months of 1981. The index reached its highest level to date in February 1981, when it stood at 273.4, then declined slightly over the next 8 months as depressed demand for petroleum lead to greater competition among producers trying to maintain their market shares. The index registered slight increases in November and December 1981 and in January 1982, largely in response to higher prices for OPEC's benchmark crude, Saudi Arabian Light, which took effect in October 1981. In February 1982, prices resumed their decline and by May, the last month for which the index has been calculated, the measure had fallen to 252.6, the lowest since December 1980.

The indexes for imports from OPEC member countries and non-OPEC countries followed the same general pattern as the index for imports from all countries between 1976 and the first 5 months of 1981. The difference between the two indexes was less than half an index point in May 1981, with the index for imports from OPEC measuring 271.6 and the index for imports from non-OPEC countries measuring 271.2. The next month, the two indexes began to diverge and at year's end stood 13.9 index points apart, with the OPEC index at 265.6 and the non-OPEC index at 251.7, off 2.2 percent and 7.2 percent respectively from May. In 1982, the difference between the indexes widened further as the non-OPEC index registered large decreases, while the OPEC index declined only slightly. In May 1982, the index for imports from OPEC was calculated at 258.6 and the non-OPEC index, at 234.5.

Of the four indexes for crude petroleum imports from selected regions, the index for the Middle East, 269.3 in May 1982, increased the most from June 1977, which equals 100. In contrast, the index for Latin America, which until June 1981 followed the same trend as the Middle East index, measured 229.8. The May 1982 index values for the other two regions, Africa and the Far East, were calculated at 251.3 and 254.5.

Among the indexes from selected countries, the index for Mexico, which measured a full 10 index points higher than any of the others as recently as March 1981, stood at 235.3 in May 1982, the lowest of the four country indexes. The May 1982 values for the other indexes were 254.4 for imports from Indonesia, 246.7 for imports from Nigeria, and 273.5 for imports from Saudi Arabia.

Revision policy. There are two factors that affect the data that are used to compute this index which could lead to revisions in previously published index values. These are (1) the timing of some of the reports that importing companies file with the Department of Energy, and (2) company or Department of Energy corrections to data on individual transactions.

Of these two factors, the first is more likely to lead to revisions. Approximately 30 percent of the data that are used to calculate the index for a given month are not available when the index is first calculated. This is the result of differences in the accounting practices of some companies: Companies that book their crude when it is loaded at the foreign port are required to report on all shipments loaded in a given month, while companies that book their crude when it lands in the United States are required to report on all shipments that land in a given month. When BLS first computes the index for the current month, the reports of many of the companies in the second group (the "landed" companies) are not available. Given the amount of data involved, it is likely that the estimate of the index for the current month will be revised when the outstanding data become available.

The second factor, company or Department of Energy corrections to data on individual transactions, has so far not been significant enough to affect aggregate index values. This is not surprising in view of the strength of the sample from which the index is calculated, and what so far has been a low incidence of corrections to data that actually enter into the calculation of the index. Users of the index should realize, however, that these kinds of corrections could affect future index values and, where the effects are significant, result in BLS' revising the index.

An analysis of the results of different calculations of the index over time has shown that index values become fairly stable 3 months after they are first calculated. In view of this, the Bureau's policy will be to revise published index values for up to 3 months preceding the current month for which the index is calculated. Revisions of index values for earlier months are not anticipated, and will not be made unless significant reporting or calculation errors are discovered, or there is a change in the Department of Energy's reporting requirements. ☐

FOOTNOTES

[1] The price index for U.S. imports of crude petroleum from all countries is published quarterly in the BLS press release "U.S. Import and Export Price Indexes." The release is available on request.

[2] The current members of OPEC are: Algeria, Ecuador, Gabon, Indonesia, Iran, Iraq, Kuwait, Libya, Nigeria, Qatar, Saudi Arabia, the United Arab Emirates, and Venezuela.

Did job satisfaction really drop during the 1970's?

Anthony F. Chelte, James Wright,
and Curt Tausky

That discontent in the American work force is rising has been a commonplace assertion in popular, and even some scholarly literature on employment for the past decade.[1] In contrast, most credible research has shown high and essentially stable levels of job satisfaction. However, a 1979 report by Graham Staines and Robert Quinn, derived from the 1977 Quality of Employment Survey (the third in the series), indicated a significant drop in the national job satisfaction level.[2] This article reviews these data and contrasts them with data from similar surveys of the same era. In general, the pattern of decline reported by Staines and Quinn is not replicated in these other surveys.

Surveys of job satisfaction began in the 1930's and have continued ever since. Regular measurements on national probability samples of the work force have been available for the past 20 years. The wording of specific questions varies among series, but all basically ask workers directly whether they are satisfied with their jobs.

Job satisfaction remained relatively stable throughout the early 1970's. Elliot Richardson reviewed the Gallup series of 1948–73 and found "scanty proof of widespread worker alienation."[3] The Gallup series registered a small drop in overall satisfaction in the later 1960's, but appropriate statistical controls for the changing structure of the labor force erased even this small trend.[4] Curt Tausky reviewed survey data from the Survey Research Center (SRC) of the University of Michigan and the National Opinion Research Center (NORC) and found that the level of job satisfaction was stable from 1958 to 1976.[5] A similar review in 1974 by Quinn and associates covered three major survey series for the period 1958–73, and concluded, "There has not been any significant decrease in overall levels of job satisfaction over the last decade." All other reviews of Gallup, NORC, and SRC data through the early 1970's have reported essentially the same.

In 1969, the University of Michigan initiated a new series on the quality of working life. The first survey, the Survey of Working Conditions, was conducted in 1969–70, and the second and third surveys, the Quality of Employment Survey (QES) were conducted in 1972–73 and in late 1977. A comparison of results of the 1969 and 1973 surveys showed no significant job satisfaction rise or decline.[6] The University of Michigan also conducted a Quality of Life survey in 1971 and in 1978. Here too, the reported levels of job satisfaction were stable. Thus, most surveys, at least through the early 1970's, conclude that job satisfaction in the American labor force has been essentially high and stable.

Two researchers report decline

The third QOE survey was reported by Staines and Quinn in 1979. A comparison of results from the 1973 and 1977 surveys showed, in sharp contrast to all prior series, a precipitous job satisfaction decline. Like all other series, the Quality of Employment surveys asked, "How satisfied are you with your job?" Between 1973 and 1977, the percentage "very satisfied" showed a modest, 5-point decline. Other indicators of job attitudes were constructed using replies from asking a number of individual questions. They are a "general satisfaction" indicator, and six facet-specific "satisfaction" indicators, which show the degree of satisfaction or dissatisfaction with certain aspects of the job, such as pay or coworkers. Both the general satisfaction indicator and five (comfort, challenge, financial rewards, resource adequacy, and promotions) of the specific satisfaction indicators show a definite and statistically significant downward trend (the sole exception is satisfaction with coworkers, which increases somewhat over the era).

Further analysis also revealed that the declines occurred in virtually every segment of the labor force. The decline was somewhat sharper for men than for women,

---

Anthony F. Chelte is writing his doctoral dissertation on the quality of work life at the University of Massachusetts at Amherst and is currently visiting assistant professor of management at West New England College. James Wright and Curt Tausky are professors of sociology at the University of Massachusetts at Amherst.

was slightly more pronounced among those in lower-skilled positions, and was more precipitous among older workers than younger ones. These variations aside, the basic conclusion of the QOE survey is that job satisfaction declined virtually everywhere in the labor force from 1973 to 1977.

Staines and Quinn advance three hypotheses to account for the downward trend. First, demographic changes in the composition of the labor force have increased the relative predominance of traditionally less satisfied workers. Second, the objective, easily identifiable characteristics of specific jobs are deteriorating. Third, workers are raising their expectations about what they seek or expect in their jobs. The first two of these are inconsistent with other data from the series. For example, the first implies that the trend would disappear with controls for the relevant demographic factors; they do not. As for the second, Staines and Quinn said that changes in the objective qualities of jobs and employment conditions between 1969 and 1977 were not great, and indicate more gains than losses. The series does not contain the data necessary to test the third item, but by process of elimination it is the most plausible.

The suggestion is thus that job satisfaction in the American labor force declined from 1973 to 1977 mainly because of rising expectations. As indicated, the sharpest evidence favoring the declining reported satisfaction conclusion is that derived from the summated indicators by Staines and Quinn in 1979. As of this writing, no analysis of trends in the component items of those indicators has been published.

The response format for the individual component items in that report is as follows: Respondents were given short statements describing various characteristics of work (for example, "the pay is good") and were then asked to state whether the statement is very true, somewhat true, a little true, or not at all true of their own jobs.

Every component item (except one) showed a decline in the percentage of "very true" responses, the drop-offs ranging from about 5 to about 15 percentage points. On the surface, then, the item-specific results sharply confirm the original Staines-Quinn conclusion.

However, more detailed consideration of these results suggests the need for some skepticism. First, the very consistency of the pattern across items is suspicious, if only because such consistent and unambiguous results are rare in social science measurement. More importantly, while the overall declines in the summated indicators seem plausible enough, some of these item-specific trends seem highly implausible. There is, for example, a 10-point drop in the percentage saying it is very true that fringe benefits are good. In fact, the same survey series shows an increase in the proportion of the labor force receiving various fringe benefits. There was another 10-point drop in "having enough time to get the job done," which on the surface suggests a massive and hitherto undetected speed-up of American industry in the span of 4 years. Many of the other specifics have this same curious character: an 8-point drop in "the work is interesting," an 11-point drop in "opportunity to develop my own special abilities," roughly a 12-point decline in "having enough help and equipment to get the job done," a 7-point drop in "the physical surroundings are pleasant," an 11-point drop in the ability to "forget about personal problems at work," and so on. On the assumption that workers themselves provide the best evidence as to the nature and characteristics of their work, these data thus suggest nothing less than a wholesale transformation of the workplace over the 4 years. It is certainly possible that such a transformation in fact occurred, but it is not very likely.

Comparison with other surveys

As noted, Staines and Quinn reported a 5-point drop in the overall proportion of workers "very satisfied" with their work. Similar, although not identical, questions on general job satisfaction were also included in two other survey series covering approximately the same span, the 1973 and 1977 NORC General Social Surveys, and the 1971 and 1978 Quality of American Life Surveys. All three series are based on representative national probability samples. The pattern reported from the Quality of Employment series is not replicated in either of the other two series, neither of which shows a statistically significant change in job satisfaction over the time span (table 1).

Another frequently employed indicator of job satisfaction or work motivation is the question, "If you were

The Quality of American Life Series contains exact replicas of nine component items; both series were products of the same organization (table 2). Sharply contrasting the item-by-item results from the employment series, identical items from the Quality of American Life series show no statistically significant declines.

Perhaps the best data ever assembled on worker expectations are those contained in the first two QOE surveys. Both surveys presented respondents with the same list of job traits and asked them to state how important each trait was. Unfortunately, the "how important" sequence was dropped in the 1977 survey.

Lacking 1977 data from this series of questions, perhaps the best remaining national data on worker expectations for the era are contained in the NORC series, which presented workers with a list of five job characteristics and asked them to rank them. On the whole, trends on these measures of "worker expectation" are modest and are not consistent with the third Staines-Quinn hypothesis. In fact, there is a slight, but statistically significant, decrease over the 4 years in the proportion ranking "work is important and gives a feeling of accomplishment" as their first preference.

Consistent with the announced decline in job satisfaction, Staines and Quinn also report a decline in overall life satisfaction, specifically, an 11-point drop in the percentage characterizing their lives as "very happy." A nearly identical question was also included in the other two series (table 3). Again, the pattern of decline indicated in the employment series is not replicated in the other two.

The Staines-Quinn findings appear implausible for the following reasons:

- The announced decline is inconsistent with a long history of prior research on job satisfaction trends, all showing high and essentially stable levels of job satisfaction.

[1] Results are based on the weighted number of respondents.

- While the overall declines on multiple-item indicators seem plausible enough, many of the trends on the specific component items seem curious and implausible.
- The drop in overall job satisfaction registered in the employment series is not replicated in either of two other series covering approximately the same time span.
- The downward trends in specific component items are not replicated in the only other national survey series containing those items.
- Three hypothesis are offered in the initial article to account for the announced decline. Two are ruled out by data from the employment series itself, and the third is not supported by independent evidence presented here.
- A parallel decline in overall life satisfaction registered in the employment series is also not replicated in two independent tests.

The announced decline may itself be in error, and job satisfaction in the American work forces may have been essentially constant during the mid 1970's. It is unclear why the QOE employment series would show a trend if one did not exist. A possible reason could be that the 1977 employment sample included only a fraction of the relatively more satisfied 1973 respondents, thus producing an artificial decline in satisfaction. Whatever the explanation, it is apparent that the 1977 employment survey contains proportionally more people who are unhappy with their jobs, and with their lives, than do other reputable national surveys of the same era. Until some plausible account of this difference is given, the results of the 1977 employment survey must be treated with some caution. □

Family Budgets

Retired couple's budgets, final report, autumn 1981

Rising medical and transportation costs contributed to the increases in the three hypothetical budgets for a retired couple. In autumn 1981, the average urban budgets were $7,226 at the lower level, $10,226 at the intermediate level, and $15,078 at the higher level (table 1). From autumn 1980 to autumn 1981, the lower budget rose 8.8 percent, the intermediate, 8.4 percent, and the higher, 8.3 percent (table 2). The increases were approximately 2 percentage points less than those reported for 1979–80, reflecting smaller increases in food.

This report is the final release of budget data for a retired couple. The expenditure data on which the budgets are based are now 20 years old. Continuation of the program would have required revision of concepts and expenditure data and extensive price collection, for which funding was not available. Therefore, the program was eliminated as part of the Bureau of Labor Statistics' recent overall budget reduction.

Consumption costs rose by 8.7 percent for the lower level budget, 8.4 percent for the intermediate, and 8.3 percent for the higher. Among the components, medical care and transportation showed the largest increases. Medical care costs increased approximately 15 percent at all three levels, while transportation costs rose about 14 percent at the lower level, 13 percent at the intermediate level, and 12 percent at the higher level. These components also showed the largest increases in the period from autumn 1979 to autumn 1980. The total cost of the medical care component for autumn 1981 contains a preliminary estimate of out-of-pocket costs for medicare.

Table 1. Summary of annual budgets for a retired couple at three levels of living, urban United States, autumn 1981

Component	Lower budget	Intermediate budget	Higher budget
Total budget[1]	$7,226	$10,226	$15,078
Total family consumption	6,914	9,611	13,960
Food	2,183	2,898	3,642
Housing	2,377	3,393	5,307
Transportation	553	1,073	1,960
Clothing	244	409	629
Personal care	198	290	424
Medical care	1,085	1,091	1,096
Other spending	275	457	901
Other items[2]	311	615	1,118

[1] Beginning with the autumn 1973 updating, the budgets no longer include income taxes.
[2] Other items include gifts and contributions and life insurance.

NOTE: Because of rounding, sums of individual items may not equal totals.

Table. 2 Percentage changes in the budgets for a retired couple, autumn 1980 to autumn 1981

Component	Lower budget	Intermediate budget	Higher budget
Total budget	8.8	8.4	8.3
Total family consumption	8.7	8.4	8.3
Food	4.9	4.5	4.6
Housing	9.6	9.2	9.2
Transportation	13.8	12.9	12.1
Clothing	3.4	3.3	3.3
Personal care	7.6	7.8	7.6
Medical care	14.9	14.8	14.9
Other family consumption	7.8	7.8	7.8
Other items[1]	8.7	8.3	7.8

[1] Other items include gifts and contributions and life insurance.

The housing component includes costs for shelter and housefurnishings and operations, and assumes that retired couples either rent or own their homes free of mortgage payments. Renter costs include average contract rent plus heating fuels, gas, electricity, water, specified equipment, and insurance on household contents. Homeowner costs include property taxes, water, refuse disposal, heating fuels, gas, electricity, specified equipment, home repair and maintenance, and insurance on house and contents.

The "other family consumption" component includes costs for reading materials, recreation, tobacco, alcoholic beverages, and miscellaneous items.

The budgets represent the costs of three hypothetical lists of goods and services that were specified in the mid-1960's to portray three relative levels of living. A retired couple is defined as a husband, age 65 or over, and a wife, who are assumed to be self-supporting, residing in an urban area, in reasonably good health, and

[1] The average costs of automobile owners and nonowners in the intermediate budget were weighted by the following proportions of families: New York, 25 percent for owners, 75 percent for nonowners; Boston, Chicago, Philadelphia, 40 percent for owners, 60 percent for nonowners; all other metropolitan areas, 60 percent for owners, 40 percent for nonowners; nonmetropolitan areas, 68 percent for owners, 32 percent for nonowners.

[2] As defined in 1960-61. For a detailed description of current and previous geographical boundaries, see the 1967 edition of *Standard Metropolitan Statistical Areas*, prepared by the Office of Management and Budget.

[3] Places with populations of 2,500 to 50,000.

able to care for themselves. The different budget levels provide different qualities and quantities of goods and services, but do not include personal income taxes. The lower budget was not designed to be a subsistence or poverty level of spending but simply somewhat lower than the intermediate budget.

The 1981 budgets were estimated by applying price changes for individual geographic areas from autumn 1980 to autumn 1981, as reported in the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W), to the appropriate autumn 1980 budget costs for each main class of goods and services. The budgets have been updated by the CPI since 1969, when the last direct pricing took place. This method of updating is approximate because the CPI reflects spending patterns and prices for commodities and services purchased by urban wage earners and clerical workers generally, without regard to the type of family and level of living and because the updating was done at a relatively aggregated level. Also, the treatment of homeownership costs in the CPI differs from the treatment in the budgets.

Cost estimates and indexes of costs for the three retired couple's budgets, by metropolitan area and regional nonmetropolitan area averages, are available from the Bureau of Labor Statistics upon request. ☐

Research Summaries

Labor force activity of women receiving child support or alimony

ALLYSON SHERMAN GROSSMAN
AND HOWARD HAYGHE

As divorce, separation, and out-of-wedlock births climbed during the 1970's, the number of mothers rearing children whose fathers were absent from the home rose sharply. Nonetheless, as the decade drew to a close, relatively few mothers received child support payments, despite the legal obligation on the part of most fathers. In addition, very few women received alimony.

A special survey conducted in April 1979,[1] shows that an estimated 2.5 million (35 percent) of the 7.1 million mothers living with children from absent fathers had received child support payments in 1978. An additional million were entitled to them but received none (table 1).

Surprisingly, mothers receiving money for child support were found to be in the labor force more often than those not awarded such support. And, women who received alimony—financial support for their personal maintenance after the dissolution of a marriage—were also more likely to work than those who did not receive such payments.

Child support recipients

In April 1979, 75 percent of the mothers who had received child support in 1978 were in the work force, and 84 percent of those employed worked full time (35 hours a week or more). Of those not awarded support, the comparable proportions were 58 percent and 78 percent. The child-support recipients were also less likely to be unemployed; at 7.3 percent their unemployment rate was only half that of the mothers not awarded support.

Although generally higher labor force participation rates and lower unemployment rates for the recipients were evident among most major age-race groups, much of the difference between the aggregate rates of the two groups was associated with other factors. That is, mothers not awarded support tended to be black, less educated, and young—groups with serious labor market problems. For example, 47 percent of the mothers not awarded support were black, compared with only 11 percent of the recipients.

Historically, black mothers maintaining their own families have had lower labor force participation rates and higher unemployment rates than their white counterparts. In March 1979, 56 percent of the blacks were in the labor force compared with 71 percent of the whites, and the unemployment rate for this group of blacks was 16 percent, compared with a little less than 9 percent for the white mothers.

Moreover, those not awarded support were, on average, younger, less educated, and more likely to be single (never married) than the recipients. About 30 percent of the mothers not awarded support were below age 25, and 42 percent had never been married. Of the recipients, 8 percent were below age 25 and less than 4 percent had never been married. Also, as shown below, proportionately twice as many mothers not awarded support had failed to complete high school:

	Not awarded support	*Recipients*
Educational attainment:		
Less than 4 years of high school	44	22
4 years of high school only	40	49
1 year or more of college . . .	16	29

Labor force

Among both blacks and whites, participation rates of recipients were higher than those for mothers awarded no support. About 76 percent of white recipients and 64 percent of the black were working or looking for work,

---

Allyson Sherman Grossman and Howard Hayghe are economists in the Division of Labor Force Studies, Bureau of Labor Statistics.

Table 1. Labor force status of mothers by child support recipiency in 1978, April 1979

Received support	2,455	34.6	1,828	74.5	1,694	83.7	16.3	134	7.3	627
Not awarded child support	2,898	40.9	1,671	57.7	1,430	78.0	22.0	241	14.4	1,228

NOTE: Sums of individual items may not equal totals due to rounding.

compared with 60 and 55 percent of the mothers not awarded support.

By marital status, divorcees were most likely to be in the labor force whether or not they received child support. Among the recipients, almost 85 percent of the divorcees were working or looking for work, compared with 69 percent of the separated women. Moreover, nearly 70 percent of the divorcees not awarded child support were in the labor force compared with 60 percent of the married women and 55 percent of those separated or never married.

Unemployment rates were much higher for those awarded no support than for recipients, regardless of race. At 11.9 percent, the unemployment rate for white nonawardees was 5 percentage points higher than for recipients, while among blacks the nonawardees were more than twice as likely to be jobless (table 2). Unemployment among mothers not awarded child support was highest for those who had never been married, partly because most were in their teens or early twenties, ages at which the already difficult problems of labor market entry are compounded by child-care responsibilities.

Income and work experience

Child support recipients had average (mean) annual incomes of about $8,940 in 1978, almost 70 percent greater than the $5,340 average for mothers not awarded support. Only part of this difference, however, can be attributed to the payments themselves; because mothers who were recipients were more likely to have earnings and other sources of income.

In 1978, overall child support payments averaged about $1,800, or only half of the difference between the incomes of the recipients and the mothers not awarded support. This is partly because women receiving child

support were more likely than those not awarded support to have had some work experience in the previous year. Nearly 80 percent of the recipients worked at some time in 1978, compared with 60 percent of those not awarded child support (table 3). Moreover, the latter tended to work fewer weeks and in lower paying jobs. Nearly the same proportions of the two groups held full-time jobs, but 54 percent of the recipients worked all year, compared with 43 percent of the others. About 2 of 3 child support recipients worked in white-collar occupations, with the remainder about equally divided between blue-collar and service occupations. In contrast, slightly over half (51 percent) of the mothers not awarded child support were blue-collar or service employees, while 48 percent were in white-collar jobs.

Alimony

Although only a very small proportion of ever-divorced or currently separated women reported that they received alimony or maintenance payments in 1978, labor force activity was strong among those who did (table 4). More than 7 of every 10 were working or looking for work. Among the women receiving alimony, those between the ages of 35 and 44 had the highest participation rates and those 45 and over, the lowest.

On average, women 45 years old and over received higher alimony payments than their younger counterparts. The higher payments probably contributed to their lower labor force participation rates, although in general, older women are usually less likely to work than younger women. These higher payments generally result from the longer duration of their marriages.

Many courts have indicated that the duration of the marriage measures the extent of the homemaker's absence from the work force and the probable degree of difficulty she will encounter in attempting to enter or reenter it. In this regard, one study concluded, that . . . "spousal support provides a form of insurance for employment benefits—e.g., work experience, accumulated earnings, pension plans and health insurance—the homemaker has bypassed so that she could devote herself to her family."[2]

Table 3. Work experience of mothers by child support recipiency in 1978

Weeks worked	Received child support	Not awarded child support
Total (in thousands)	2,455	2,898
Worked	1,942	1,738
Percent of total	79.1	60.0
Worked (percent)	100.0	100.0
Full time	80.7	75.8
40 weeks or more	61.9	51.3
50 to 52 weeks	53.7	43.4
39 weeks or less	18.8	24.5
Part time	19.3	24.2
40 weeks or more	8.1	10.0
50 to 52 weeks	6.0	7.1
39 weeks or less	11.2	14.2

Table 4. Labor force status of ever-divorced or currently separated women who received alimony or maintenance payments in 1978, by demographic characteristics, April 1979

[Numbers in thousands]

Characteristics	Total	In labor force		Not in labor force
		Number	Participation rate	
Total, ever-divorced or currently separated	14,334	8,655	59.8	5,768
Alimony or maintenance payment recipients	528	373	70.6	155
Race and Hispanic origin:				
White	486	340	70.0	146
Black	41	32	(1)	9
Hispanic	24	19	(1)	6
Age:				
18 to 24 years	26	19	(1)	7
25 to 34 years	135	99	73.3	36
35 to 44 years	188	150	79.8	37
45 years and over	179	105	58.7	74
Median payments in 1978	$1,570	$1,420	—	$1,810

[1] Rate not shown where base is less than 75,000.

NOTE: Sums of individual items may not equal totals due to rounding.

IN THE UNITED STATES, there is a clear-cut legal obligation for fathers to provide financial support for their children from a marriage ending in divorce or separation regardless of the labor force status of the mother. Moreover, they are obligated to support children born out of wedlock providing paternity has been proven.[3] Yet, as this report demonstrates, the receipt of child support is not widespread. ☐

FOOTNOTES

[1] The estimates in this report are based on data that were collected in March and April 1979 from the Current Population Survey (CPS) conducted for the Bureau of Labor Statistics by the Bureau of the Census. About 56,000 households in 614 areas of the United States with coverage in each of the 50 States and the District of Columbia were eligible for interviews in March. About 40,000 of these households were reinterviewed in April and women, 18 years of age and over, were then asked supplementary questions regarding child support and alimony payments. The labor force estimates shown in this report were derived from special tabulations prepared by Bernard R. Altschuler of the Data Services Group, Office of Current Employment Analysis, Bureau of Labor Statistics.

Estimates based on a sample may vary considerably from results obtained by a complete count, especially in cases where the numbers are small. Therefore, differences based on these estimates may not be significant.

For more detail and the interpretation of such differences, as well as a detailed discussion of the survey methodology and findings, see: *Child Support and Alimony: 1978, Current Population Reports*, Series P-23 no. 112 (Bureau of the Census, 1981).

Does a younger male labor force mean greater earnings inequality?

MARTIN DOOLEY AND PETER GOTTSCHALK

In a recent article in the *Monthly Labor Review*, Peter Henle and Paul Ryscavage showed that inequality of earnings among men grew between 1959 and 1977, although the rate of increase was lower after 1973.[1] Robert Plotnick likewise found an increase in the overall variance of men's earnings during the 1958–77 period.[2] Did this widening disparity reflect more than the effects of changes in the age composition of the labor force?

The answer to this question is important for public policy. If the greater inequality of earnings only reflects growth in the proportion of young males in the labor force as a result of the baby boom, then we might expect a reversal of the trend in the future. As this disproportionately large group of young men ages and is replaced by smaller cohorts, the distribution of earnings may become more equal. More disturbing would be the finding that inequality has grown among men with a given level of work experience. This would indicate that the greater overall inequality reflects more than simply the "younging" of the labor force.

Our analysis makes two contributions to the growing literature on earnings inequality. First, by focusing on inequality within education-experience groups, we demonstrate that two simple demographic explanations are not sufficient to explain the trend. Finis Welch and Richard Freeman have shown that the mean earnings of young workers fell relative to the mean earnings of older workers during the late 1960's and early 1970's.[3] This by itself would increase the between-age-group variance of earnings, and hence, increase the total variance. However, we show that, even after the influence of the between-group variance is eliminated, there remains a substantial trend towards greater inequality. The second demographic explanation is that the young make up a growing percentage of the labor force. Because the young typically have a high earnings variance,[4] the average of the within-age-group variances would tend to increase with the labor market entry of the baby boom. But by examining the variance of separate education-experience categories, we show that this factor is not sufficient to explain the trend in the overall variance. Our principal concern is with the experience composition of the labor force, but because Jacob Mincer has shown that earnings inequality varies with the level of education,[5] we control for this factor as well.

The second major contribution of this study is to show that the proportion of people with zero earnings also increased within education-experience categories. This development has largely been ignored in the literature. Henle and Ryscavage and Plotnick limited their samples to people with positive earnings. Likewise, our measure of inequality, the variance of the logarithm of earnings, does not allow us to include people with zero earnings. The exclusion of a growing group of individuals who fall at the lowest point in the distribution gives an incomplete picture.

Method of the study

To examine these issues, we start by reviewing our measures of inequality and zero earnings averaged across all education and experience groups. We then turn to an analysis of changes within education and experience categories.

Like Henle and Ryscavage, we used data from the work experience supplement to the March 1968–79 Current Population Survey.[6] The special household questionnaire included data on annual earnings and weeks worked. Our sample covered males 16 through 62, who were not then in school and who reported they had worked 50 to 52 weeks the previous year, or fewer weeks for reasons other than school or, in the case of older men, retirement. Those self-employed or working without pay were excluded. The observations were divided into four education categories: less than 12 years, 12 years, 13 to 15 years, and 16 years or more of schooling completed. Current age minus estimated labor force entry age was used to allocate individuals to single-year labor force experience groups.[7]

Within each of the 1,960 education-experience-year cells, we calculated the variance of log annual and log weekly earnings among earners, as well as the proportion of zero earners. (Weekly earnings are not collected directly from respondents to the March Current Population Survey. For this study, estimates of weekly earnings were obtained by dividing the respondent's reported annual earnings by reported weeks worked. The weeks worked may have been full time, part time, or some combination of the two.) These within-group measures are the basis for our analysis. Inequality of weekly earnings, which has the advantage of not being influenced by changes in the distribution of weeks worked, was not studied by Henle and Ryscavage or Plotnick.

The findings

Table 1 shows the total variance of log earnings and the weighted average of the within-group variances for

each year.[8] The average was constructed by weighing the variance of each of the education-experience cells by the proportion of people in that cell in that year. Column 1 shows that the total variance of log annual earnings grew substantially over the period. The rate of increase, however, seems to have been more rapid prior to 1973, confirming Henle and Ryscavage's earlier conclusions based on gini indexes.[9] Column 2 shows that the increase in the total variance occurs even when we eliminate the effect of changes in between-group variance. The average of the within-group variances of log annual earnings increased from .373 in 1967 to .454 in 1978. Examination of the data again indicates that the growth rate was considerably higher during 1967–72 than in the 1973–78 period.

To estimate growth rates, we fit linear time trends to the data in table 1. A spline covering the 1973–78 period was used to test for change in growth rates.[10] The estimated trend over the full period, the trend over 1967–72, and the change in the trend after 1972 are shown in the bottom three rows.[11]

The time trends fitted to the variance of the log annual earnings indicate a 2.8-percent growth rate in the total variance and a 2.5-percent growth rate in the within-group variance over the full period. This was a result of a very rapid rise between 1967 and 1972 and a leveling after 1972. Columns 3 and 4 of table 1 show that the increasing inequality of annual earnings is not only a reflection of changes in employment patterns. The total variance of weekly earnings also shows a 1.3-percent growth rate and the within-group variance shows a 0.9-percent growth rate; both are statistically significant. Again, the growth rates are substantially higher during 1967–72 than in the later period, when the growth rates are quite small. These data indicate that annual and weekly earnings among workers with positive earnings have become less equal, although the rate of increase in the inequality dropped after 1972.

Column 5 shows the percent of males with zero earnings. This series shows a dramatic increase during the survey period. In 1967, 3.3 percent of all men in our sample had zero earnings. By 1978, the proportion had grown to 6.4 percent. The growth rates over the full period and the period 1967–72 are both large and significant. For the percent with zero earnings, the trends in the two subperiods are not significantly different.

The rise in the proportion of men with zero earnings is large enough to warrant careful attention. While it is beyond the scope of this study to explain why this rapid increase has occurred, it is consistent with other survey data which show that the proportion of men out of the labor force in any given month has been growing.[12] More surprisingly, our data indicate that many of these men did not have any earnings during the year.

Table 2 shows the estimated growth rate in the proportion of men with zero earnings and the estimated growth rate in the within-group variance of log annual and weekly earnings for 16 education-experience categories.[13] Columns 1 to 3 indicate that the within-group variance of log annual earnings increased in all cases. All growth rates except two are significantly greater than zero (the exceptions being the two highest experience groups for college graduates). The growth rates are both statistically significant and of substantial magnitude. The within-group variance of the log of annual earnings grew in the 2- to 4-percent range for most categories. This indicates that the average increase in the within-group variance of log annual earnings shown in table 1 reflects more than population shifts among cells as a result of the baby boom.

For the group with the lowest experience there is strong confirmation of a slowdown in the trend toward inequality, even within experience categories. Column 3 shows statistically significant declines for all educational levels. For other experience groups, the picture is not so clear. Column 3 shows a decline in the growth rates for all but three of the categories with more than 10 years of experience. However, almost none of these differences in the growth rates is statistically significant. This partially reflects the substantial year-to-year fluctuations in the data that make it difficult to draw conclusions about subperiods. Nevertheless, we can say that a decline in the trend toward greater inequality within education-experience categories is not strongly confirmed by the data for men with more than 10 years of experience.

Columns 4 to 6 show the growth rates in within-group variances of log weekly earnings. As found in table 1, the growth rates are considerably lower than those for the log of annual earnings. In addition, we find that (with one exception) the trend toward greater inequality of weekly earnings is statistically significant only for men with less than a college degree and less than 21 years of experience. For these people, growing inequality of annual earnings also reflects growing inequality of weekly earnings. For the other groups, all but one trend coefficient in column 4 is positive but only one of these is statistically significant.[14] Few of the education-experience groups show statistically significant changes in growth rates between the two subperiods.

Columns 7 and 8 show the growth rates in the percent of men with zero earnings. Column 7 shows significantly positive growth rates in the proportion of respondents with zero earnings, even in the higher education-experience cells. Not only are the growth rates in columns 7 and 8 statistically significant but they are quite large, almost all being above 7 percent per year. Columns 8 and 9 indicate that the growth rates in the percentage of zero earners did decline after 1972. However, the statistically significant declines are concentrated in the two groups with lower experience.

IN SUMMARY, we find that the increasing inequality of male earnings reflects more than the changes in the composition of the labor force which resulted from the labor market entry of the baby boom. Even within education-experience cells, the variance of log annual earnings has been increasing. For men with less than 20 years of experience, the variance of log weekly earnings has also been rising. Furthermore, there is an increasingly large proportion of men who earn no income over a full year. The rise in this proportion of zero earners is not confined to those with little education or experience. It seems to be occurring across the board.

What are the possible explanations for our observed inequality *within* education-experience cells? One might be that increased transfer programs have generated disequalizing labor supply responses. But while this hypothesis has yet to be tested rigorously, indirect evidence suggests that it is not a full explanation. Recall, for example, that high education-experience males, whose greater earnings capacity makes them less likely to be eligible for transfer payments, also experienced an increase in inequality. This suggests that expanded transfer programs were not the only factor at work. Another possible explanation involves the education and

training investment decisions of persons born during the baby boom. Increasing inequality of human capital investment among members of recent cohorts may have led to increased earnings inequality, especially during the early years of the life cycle. In an earlier study, we provided both theoretical and empirical support for this hypothesis. Including a measure capturing baby boom effects reduces the trend toward inequality but does not eliminate it.[15] A more satisfactory explanation for the trend towards greater inequality, both within demographic groups and within occupations (as shown by Henle and Ryscavage), therefore, remains an important topic for further research. □

[5] See Jacob Mincer, *Schooling*.

[6] The March work experience supplement is a retrospective survey which asks respondents to describe their own labor force experience and that of other household members for all of the previous calendar year.

[7] Finis Welch and William Gould used data from the 1940, 1950, 1960, and 1970 censuses and the Coleman-Rossi sample to estimate labor force entry age for men conditional on observed age, education, and birth cohort. These data were kindly provided to the authors by Finis Welch. Current age minus estimated labor force entry age was used to estimate labor force experience. See Finis Welch and William Gould, "An Experience Imputation or an Imputation Experience," unpublished paper (Los Angeles, University of California, October 1976).

[8] The between-group variance in each year is simply the difference between the total and the average within-group variance shown in table 1.

[9] See Henle and Ryscavage, "The distribution of earned income."

[10] The time trends in table 1 are estimated by fitting a time trend and a spline (which is a variable which takes on the values 1, 2 . . . n in the n years following 1972, allowing the fitted time trend to kink in 1973) to the 12 yearly observations for each series. The dependent variables are the logarithms of the averages shown in table 1.

An alternative procedure is to use observations on each category in each year, yielding 1,960 observations for each regression. Because these observations can be grouped exactly on the 12 yearly values of the independent variables, this procedure is identical to estimating equations using the time trend and spline as independent variables and the average of the logs, rather than the log of the averages, as dependent variables. The trends based on this alternative procedure give the same qualitative results.

[11] The 1973–78 trend can be obtained by adding the bottom rows.

[12] For example, see Donald Parsons, "The Decline in Male Labor Force Participation," *Journal of Political Economy*, February 1980, pp. 117–34.

[13] The trends in table 2 are calculated as follows: The 1960 single year-experience-education categories, which make up our basic data, are aggregated into 192 categories made up of 16 experience-education cells observed in each of 12 years. The single year-experience-education data are used to calculate weighted averages of the two variables shown in table 2 (percentages of zero earners and within-group variances) for each of the 16 categories for each year. Time trends are fitted to the log of these averages within each aggregated category. Again, the alternative procedure of fitting trends to the averages of the logs gives similar results.

[14] Entering the unemployment rate in the regression used to estimate the trend does not alter the basic conclusion. Time trends still tend to be insignificant for all but the groups with the least education and experience.

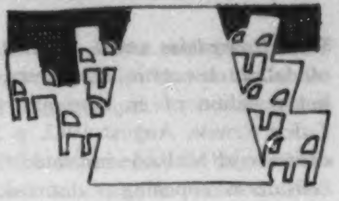
Developments in Industrial Relations



Legislated settlement ends rail strike

In late September, President Reagan signed into law a legislated settlement (P.L. 97-262) to end a 4-day strike by about 26,000 members of the Brotherhood of Locomotive Engineers. The strike had curtailed rail freight and passenger service across much of the country. At issue in the dispute was the Locomotive Engineers' right to strike should they fail to maintain their traditional pay differential over other operating employees represented by the United Transportation Union if those employees negotiate "crew consist" agreements providing additional compensation in return for a reduction in crew size. The Locomotive Engineers have had such a strike provision in their contracts since 1975.

The legislated settlement preempted this right and implemented other recommendations of an emergency board established by the President in July. Under provisions of the Railway Labor Act, the President can establish such a board if negotiations and mediation reach an impasse, at which time a 60-day "cooling-off period" begins. In mid-August, the board recommended that the union accept the national railroad wage-and-benefit pattern and that the union be allowed to negotiate changes in engineer compensation when there is a "change in the compensation relationship as a result of a crew consist agreement between a given carrier and the United Transportation Union." However, the board also said that during the life of the agreement the Locomotive Engineers should only negotiate "within the peaceful procedures of the Railway Labor Act."

When the "cooling-off period" (which had been extended 10 days) expired on September 19, the Locomotive Engineers walked off their jobs. This prompted President Reagan to ask the Congress to pass emergency legislation conforming to the emergency board's recommendations to end the strike. The Congress passed the measure on September 22.

In signing the legislation, the President noted that "vital national interests" had been at stake and that a prolonged strike could have idled "nearly a million Americans"—primarily in the rail, auto, steel, and mining industries, and also have an adverse effect on the agricultural products industry. The mandated settlement provided the same general wage-and-benefit terms as those already negotiated in the railroad industry by 11 other unions, some of which had settled as early as November 1981. (See *Monthly Labor Review*, January 1982, p. 24.) Members of the United Transportation Union were voting on a pattern agreement negotiated in September.

Pre-bargaining talks end at aluminum companies

Discussions between three major aluminum companies and the United Steelworkers did not result in labor cost concessions the companies had sought. However, a union official said that the talks had "cleared the air on a number of issues" in preparation for the 1983 bargaining. The union's existing 3-year contracts with the Aluminum Co. of America, Reynolds Metals Co., and Kaiser Aluminum & Chemical Corp. expire May 31, 1983. In recent years, the Steelworkers' settlement with these companies has set a pattern for workers it represents at other aluminum companies, as well as for the Aluminum, Brick and Glass Workers union, which represents 20,000 employees of Alcoa, Reynolds, and other companies. Overall, the Steelworkers represents 25,000 employees in the industry.

The Steelworkers apparently ended talks because the Aluminum Workers rejected any negotiation with the industry, which meant that any concessions by the Steelworkers would end compensation parity in the industry. At the time the talks were terminated, the three companies were operating at less than 50 percent of capacity and, reportedly, their output was selling below the cost of production.

Steel industry update

There was renewed hope in the steel industry that the Steelworkers and the eight Coordinating Committee

---

"Developments in Industrial Relations" is prepared by George Ruben and other members of the staff of the Division of Developments in Labor-Management Relations, Bureau of Labor Statistics, and is largely based on information from secondary sources.

Steel Companies could reach a pattern-setting accommodation on cuts in labor costs, despite the union's earlier rejection of an employer proposal. (See *Monthly Labor Review*, August 1982, p 56.) Steelworkers President Lloyd McBride indicated the union was willing to consider a reopening of discussions with the companies, which were operating at less than 40 percent of capacity, with some 120,000 workers on layoff.

Despite the uncertain outlook for an early settlement with the eight companies, other individual companies were able to reach wage concession agreements with the Steelworkers:

- Employees of Phoenix Steel Corp.'s Claymont, Del., plant agreed to an immediate $1.25 an hour wage cut, to be followed by a 25-cent cut in January 1983. Both reductions will continue to the August 1983 termination of the current 3-year contract. Workers at the company's Phoenixville, Pa., plant rejected a similar proposal, but negotiations were continuing. Half of the 1,800 workers at the two specialty steel plants were on furlough.
- In Illinois, 1,300 workers at Northwestern Steel & Wire Co.'s wire and rod mill agreed to reductions in pay and holidays amounting to as much as $3 an hour, according to the company. Company President Peter Dillion declined to estimate the total savings to the company but said the operation had lost money for the last 3 years. The settlement was impelled by the company's July 20 announcement that it would close the mill in 90 days if the workers did not agree to cuts in compensation.
- Colt Industries Inc. again announced plans to close its Crucible Stainless & Alloy Division mill in Midland, Pa., by yearend. However, Colt did indicate that the plant was still for sale; earlier purchase negotiations with Cyclops Corp. were not successful. The company currently has 275 employees, compared with a peak of 5,500 in 1980.
- In West Virginia, the 11,000 employees of National Steel Corp.'s Weirton Steel Division retained Lazard Freres & Co. to help in their efforts to purchase the operation. The investment banking firm will assist in forming a stock ownership plan, negotiating a purchase price, getting financing, and evaluating Weirton's assets.
- Republic Steel Corp. announced a 7- to 10-percent pay cut for 5,800 nonunion salaried employees. Earlier this year, Republic had frozen cost-of-living salary increases and merit pay increases for salaried employees and had reduced their numbers by 1,400.

Company besieged by claims, files bankruptcy

In action that may have widespread implications for other asbestos producers and processors—and for companies in other industries—Manville Corp. filed for bankruptcy, asserting that its assets were insufficient to meet the projected costs of thousands of lawsuits filed by workers claiming physical disabilities resulting from exposure to asbestos. John H. McKinney, Manville's chairman and president, explained that "our businesses are in good shape despite this recession . . . [but] we are completely overwhelmed by the cost of the asbestos health lawsuits filed against us." At the time, there were 16,500 claims pending against Manville, with 500 being added each month.

Manville apparently decided to seek protection under Chapter 11 of the Federal Bankruptcy Act of 1978 after a study by Epidemiology Resources, Inc., indicated that Manville faced a potential total of 52,000 suits at a possible cost of $2 billion, nearly twice the company's current $1.1 billion net worth. Officials said this was the "low projection"; the "high projection" was for 120,000 suits at a liability of more than $5 billion.

In recent years, Manville and other asbestos producers and users have been hit by medical claims and have been asking the Federal Government to assume a major share of the cost because many of the workers incurred cancer or asbestosis from exposure to asbestos during wartime service in shipyards. Dave Pullen of the Asbestos Compensation Coalition (nine firms that either manufacture asbestos or did so in the past) maintains that the Government has a degree of responsibility because it "acted just like any other manufacturer. They bought and sold asbestos fiber, they purchased machinery to give to asbestos manufacturers, they specified the products and controlled the workplace where most of those workers were exposed."

Initial indications were that this position was not favored by the Congress. Senator Robert Dole, chairman of the Subcommittee on the Courts, criticized Manville's decision to file under the bankruptcy act, saying "this procedure is dubious, and unusual at best. America's bankruptcy system can ill afford the additional strains to be placed upon it by those who would use its protection for shelter against personal or corporate attacks where other remedies, both legal and congressional, would seem to be more appropriate."

Attorneys for many of the claimants also reacted bitterly to Manville's action, calling it improper because the company was viable despite a $19.9 million loss during the second quarter of the year.

Actually, Manville was not the first asbestos company to file under Chapter 11. A month earlier, UNR, a Chicago company, had sought protection under the chapter, which suspends creditor claims while the company attempts to reorganize and improve its financial condition.

There were no immediate indications of how other asbestos companies would handle their claims. At the time of the Manville action, 260 other asbestos companies faced a total of 13,500 claims.

Texaco settles, 7-month strike ends

The round of bargaining in petroleum refining was finally concluded when Texaco, Inc., and the Oil, Chemical and Atomic Workers agreed on a contract that ended a 7-month strike at the company's Port Arthur, Tex., refinery. The major issue in the dispute arose in 1976, when Texaco began reducing the optional lump-sum payment retiring workers may elect instead of the usual monthly benefits. The company claimed the reduction was justified because rising interest rates would have enabled workers investing their lump sum to exceed the total value of monthly benefits drawn by other retirees. The dispute accelerated in 1981, when the union initiated and won a Federal District Court case concerning Texaco's action. At the time of the accord, the court was considering Texaco's appeal.

The parties agreed to an out-of-court settlement of the legal dispute. The accord provides for the reduction of lump-sum benefits to apply to future retirees. However, the 542 workers who retired and elected lump-sum payments between February 1976 and January 1982 will share $3 million provided by Texaco. In addition, future retirees will be credited with up to 5 years of service time lost because of strikes or union duties. Future retirees also can get credit for other time lost by paying an amount equal to 4 percent of base pay for the period lost.

The 3½ year agreement also called for wage increases of 9 percent, effective immediately, and 90 cents an hour, effective June 15, 1983. (This matches increases provided by 2-year agreements the union had negotiated with other refineries earlier in the year.) In 1984 and 1985, Texaco workers will receive the same wage increases as those resulting from the 1984 bargaining at the other companies.

In an effort to reduce its work force, Texaco agreed to pay employees who quit before they are eligible to retire $4,000 plus 1 week of pay for each year of service. Texaco said it was necessary to reduce the refinery's hourly work force by 1,000 persons because of a worldwide glut of petroleum products.

Texaco kept the Port Arthur refinery in operation during the strike, using nonunion technical and management employees.

Glass workers trade wages for job security

More than 5,000 glass workers were covered by a settlement between Libby-Owens-Ford Co. and the Glass and Ceramic Workers that a company official said "provides greater job security . . . in return for reducing future wage costs." At the time of the settlement, 2,000 hourly employees were on layoff attributed to the depressed condition of the housing and automobile industries.

The new contract, which supersedes the balance of a 3-year contract scheduled to expire in October 1983, runs to October 1985. Under the agreement:

- The union gave up 19-cent-an-hour wage increases scheduled for October of 1982 and 1983, but there will be a 19-cent increase in October 1984.
- The provision for automatic quarterly cost-of-living pay adjustments was suspended, subject to activation if the BLS Consumer Price Index for Urban Wage Earners and Clerical Workers (1967=100) rises more than 33.6 points. Part of the suspended adjustment will be recovered by the employees if parts shipped to the automobile industry reach specified levels.
- Provisions for October 1982 pension and insurance improvements were retained.
- Libby-Owens-Ford agreed to establish a $800,000 fund to pay health insurance premiums for laid-off workers, retirement incentives, or as lump-sum payments to active employees. Each local union will decide how to use its share of the fund.
- Libby-Owens-Ford agreed not to expand glassmaking or auto glass fabricating furnaces at plants where workers are not represented by the union.
- The parties agreed to reopen negotiation in October 1984 if hours worked by members of the bargaining unit drop below a specified level.

The contract covered operations in Toledo, Ohio, Ottawa, Ill., Charleston, W.Va., and Lathrop, Calif.

Newspapers begin cost-reducing measures

More than a year of uncertainty over the fate of the financially troubled *New York Daily News* was ended when the last of the newspaper's 11 unions agreed to a package of cost-reduction measures. Details of the package varied among unions, but the overall objective was to reduce labor costs by $50 million a year, the minimum cut the paper said was necessary for continued operation. The reduction was to be attained by eliminating the equivalent of 1,340 full-time employees from the work force. To help do this, the newspaper set up a $50 million fund to finance one-time "buy-out" payments for full-time employees who elect to leave. The *Daily News* also agreed to spend $44 million to upgrade its printing plant in Brooklyn and establish two suburban plants.

The accord called for (1) a 3-year extension of the current labor contracts, which had been scheduled to expire in March 1984, (2) weekly wage increases of $38,

$35, and $37 in March of 1984, 1985, and 1986, (3) a cost-of-living wage adjustment clause that could result in additional increases, and (4) a possible reopening of bargaining if the paper attains a profit that exceeds 6-percent of net worth.

The unions had agreed to reopen their current 3-year agreements (which were not scheduled to expire until March 1984) in response to a request by the parent Tribune Co. of Chicago, which cited a 1981 operating loss of $13 million and an expected 1982 loss of $30 million. The effort to save the morning tabloid came after the Tribune Co. had failed to sell the paper, which has a circulation of 1.5 million on weekdays and 2.2 million on Sundays.

Elsewhere in the industry, the *Minneapolis Star and Tribune Co.* announced that it will allow 825 nonunion employees to take up to 30 days off without pay, with an option to take more. A company official said the program will reduce payroll costs and give employees more leisure time, and that a similar program will be discussed with union-represented workers if they expressed an interest. The *Minneapolis Star* and the *Minneapolis Tribune* merged in April in an effort to reduce payroll and distribution costs.

Iron Workers pay frozen for 1 year

In Arizona, members of Iron Workers Local 75 approved a 1-year contract that freezes their pay rate at $16.25 an hour for 1 year but does provide for a 20-cent-an-hour increase in employer financing of benefits. The agreement was negotiated with the Arizona Steel Field Erectors Association. Harry Steel, business manager of the local, explained, "We have a lot of unemployment and a lot of our people are moving out of the State, so we thought it was best to hold the line until things get better." Currently, about 30 percent of the local's 1,500 members are unemployed.

Delta nonunion workers get pay increases

Delta Airlines granted its 33,000 nonunion employees general and merit pay increases totaling up to 8 percent, along with improvements in benefits. (The changes did not apply to Delta's 4,000 pilots, who are covered by a contract that calls for periodic improvements in pay and benefits.) Delta suffered an operating loss for the quarter ending March 31, 1982—its first quarterly loss in 25 years—but rebounded and showed a net profit of $20.8 million for the fiscal year that ended June 30.

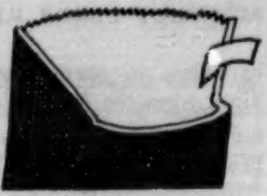
Teamsters' pension fund monitoring extended

A quarter century of controversy concerning the Teamsters' Central States Pension Fund was eased when fund trustees and the Department of Labor entered into a consent decree that will extend Federal monitoring and independent management of the fund's assets for at least 10 years. The decree opened the possibility of settling several Federal suits involving the fund. In the most important suit, filed in 1978, the Government accused Teamsters' President Roy L. Williams and 18 other former trustees of "gross mismanagement" of millions of dollars of fund assets. The trustees had resigned a year earlier, under pressure from the Department of Labor and the Internal Revenue Services.

Secretary of Labor, Raymond J. Donovan, said the decree contains "virtually all of the safeguards that the Government has been seeking . . . [to] assure that the assets of the Teamsters' pension fund are protected and managed prudently and professionally.

The decree contains provisions to (1) require the fund to use an independent assets manager (as before, the manager is permitted to consult with the trustees, but trustees cannot veto the manager's investment decisions); (2) permit the trustees to fire the investment manager and hire a replacement, subject to approval by the court; (3) create an independent special counsel, to be selected by the court, to monitor operation of the fund and periodically report the results to the court; (4) remove fund trustees and employees convicted of certain "relevant" crimes, such as fraud or embezzlement; and (5) continue the court's jurisdiction over the fund for 10 years, for an additional 5 years if the Department of Labor insists, and beyond that "for good cause shown." ☐

Book Reviews



Holy macro! Inflation's not that simple

Commodity Prices and the New Inflation. By Barry P. Bosworth and Robert Z. Lawrence. Washington, The Brookings Institution, 1982. 215 pp. $24.95, cloth; $9.95, paper.

The traditional division of economic theory in college textbooks between microeconomics (dealing with such topics as the theory of the firm, market structures, and price determination) and macroeconomics (dealing with such topics as business cycles, inflation, and unemployment), while a useful pedagogical tool in many respects, may also tend to obscure some crucial connections in the real world. It is particularly important to realize that the effectiveness of macroeconomic policy alternatives such as anti-inflation remedies may be highly dependent on the microeconomic forms of market structure and industrial organization prevailing within the economy.

This point is central to the analysis presented by Barry Bosworth and Robert Lawrence in their new book, *Commodity Prices and the New Inflation.* They contend that we cannot rely on macroeconomic measures alone to contain inflation without sacrificing real output and employment because the American economy is a thorough mixture of "auction markets," where prices are largely determined by competitive forces, and "customer" or "fixed-price" markets, where prices are set in at least a partially monopolistic environment.

This distinction between "perfect" and "imperfect" competition has been a staple of microeconomic theory for almost half a century. The implications of this distinction for macroeconomic stabilization policies have seldom been well appreciated, however. Bosworth and Lawrence observe that, on one hand, if the economy were dominated by markets fitting into the competitive model, then "fiscal and monetary policies would be an adequate basis for controlling inflation." If, on the other hand, "all prices and wages reflected the outcome of a bilateral monopoly or fixed-price model," then some variation of incomes policies might be effective. "But since the actual economy is a mixture of market structures," the authors conclude, "either of these policies will be frustrated when used alone." Given these circumstances, the authors summarize the basis for their emphasis on control of supplies of primary agricultural and energy commodities as a critical element in any comprehensive anti-inflation program:

> Any attempt to stabilize the overall price level by inducing a price change in the inflexible sector to offset changes in the sensitive sector might prove far more costly than stabilizing the price in the sensitive sector itself. Indeed, it is the extreme sensitivity of commodity prices to changes in demand and supply that suggests that control over supplies in these markets is likely to be more efficient than control over the aggregate money supply. This does not mean that monetary policy should be abandoned as a weapon against all types of inflation but rather that it should be supplemented in the case of commodity price changes. In fact, macroeconomic policy is of great importance to primary commodity markets, which need a stable environment to function efficiently.

Bosworth and Lawrence focus on the pivotal role played by primary commodity prices in the wide fluctuations in the level of inflation during the 1970's, not only in our own country, but in Western Europe and Japan as well. They concentrate on the determinants of agricultural and energy prices; while prices for many other raw commodities were also quite volatile during the past decade, the authors cite evidence to demonstrate that "their impact on the average price level was small because the value of their use is small as a share of total GNP." In this country, consumption of these other raw materials amounts to less than 4 percent of the gross national product.

One of the more intriguing aspects of the authors' analysis of farm price movements since 1970 is their explanation of how a mere 3 or 4 percent drop from the trend of world production of cereals (that is, grains and rice) in 1972–73 led to a doubling in these prices. Bosworth and Lawrence give relatively little weight to several popular explanations, such as the long-term rise in world demand for livestock products and hence cereals. They fix a large share of responsibility instead on short-sighted government policies here and abroad. For example, the American government had decided by the early 1970's to let our domestic grain reserves drain to appease both farmers worried about the reserve's depressing impact on grain prices and consumers complaining about the reserve's costs. At the same time, many foreign governments had chosen to insulate their populations from sudden shifts in world farm prices by controlling retail food price movements, thereby failing to restrain demand in times of shortage. Thus, when the Soviet Union unexpectedly emerged as a major grain purchaser at a time when our reserves were already down and world demand was still high, American consumers were forced to bear the brunt of the inevitable adjustment process through both skyrocketing prices and reduced food consumption. More suitable government policies could have spread the burden more evenly and would not have led to such an inflationary outcome.

The shifting balance of power between the oil-producing companies controlled from the industrial West and the oil-producing countries of the Third World receives considerable attention from the authors. They remind us with painful clarity that few in the West realized the potential strength of the Organization of Petroleum Exporting Countries (OPEC) until the 1973 oil embargo, even though in retrospect the signs of OPEC's growing power were obvious long before. They demonstrate that the two major oil crises of the 1970's "were not marked by big declines in supply but rather by panicky inventory hoarding in response to expected shortfalls." Policies to influence consumer psychology are therefore an integral part of any strategy to help prevent or alleviate recurrences of steep runups in oil product prices.

The authors realize that choosing and implementing the right mix of policies targeted at constraining commodity prices in international markets will not be easy. In general, Bosworth and Lawrence support a series of sophisticated commodity reserve policies that might require more coordination between nations than has hitherto been attainable. The authors explain quite convincingly why they reject traditional multinational reserve and commodity stabilization agreements, which they view as "inherently unstable" for political as well as economic reasons. Bosworth and Lawrence see more hope, for example, in a network of bilateral agreements on grain reserves that would allow contracting countries to take care of each other's grain import or export needs within predetermined price ranges, leaving countries outside the network to adjust to any major supply disruptions or gluts in the "residual market." These and other targeted microeconomic policy recommendations may prove to be the most controversial part of the book, even for those of us who agree that macroeconomic stabilization policies by themselves are inadequate.

Commodity Prices and the New Inflation is an exceptionally well written and cogently argued book that makes a valuable contribution to understanding how the contemporary economy works—or, more pointedly, why it hasn't worked so well in recent years. Bosworth and Lawrence's synthesis of macro- and microeconomic theories is quite successful, I believe, as is their analysis of the mistakes that have plagued public policies so often. Their advice for solving the problems confronting us, however, is still very much open for debate. They freely draw upon a wealth of empirical studies conducted by other economists without burdening the book with esoteric mathematical exercises. This is a work for any economically literate person interested in pondering the dilemmas of stagflation.

Turning point in current thinking

The Crisis in Economic Theory. Edited by Daniel Bell and Irving Kristol. New York, Basic Books, Inc., Publishers, 1981. 226 pp. $15.50, cloth; $6, paper.

This book comprises a series of essays originally published in the 50th anniversary issue of *The Public Interest* magazine. The essays run the gamut of contemporary economic theory—from the rational expectations theorists and monetarists to the Post-Keynesians and Marxists. The common theme integrating the different perspectives is the belief that the synthesis of Keynesian and neoclassical economics, which provided a basic rationale for economic policy in the generation after World War II, has become irrelevant, if not misleading. This theory became outmoded in the 1970's as simultaneous inflation, recession, and unemployment came to characterize capitalist economies.

In the "golden age" of the neoclassical synthesis, 1947 to 1973, democratic capitalist nations generally accepted the Keynesian thesis that the central government's budget through its taxing and spending programs could serve as an economic balance and stabilize economies at high employment levels. The advent of annual national income accounting, computerized econometric models, and the availability of reliable and current unemployment data from the Current Population Survey appeared to provide a basis for utilizing Keynesian theories as operational tools in planning for economic growth.

The Employment Act of 1946 and the establishment of the Council of Economic Advisers represented official recognition that the thrust, if not the specific details, of the Keynesian theory, had become an important foundation of government policy. The Keynesian system was supplemented by the widespread acceptance of the Phillips curve analysis suggesting that governments could choose among unemployment rate goals depending on the rate of inflation they were prepared to accept.

The strength of the neoclassical synthesis was its integration of a role for government in determining the overall level of economic activity with the maintenance of a predominant role for competition and market pressures in individual sectors of the economy. The primary flaw with the theory in the 1970's was the contradictory policy options it implied. To reduce inflation, the Keynesian diagnosis pointed to the need for a surplus in the Federal budget to drain off purchasing power from the economy. To counter rising unemployment, the theory recommended that the government operate at a deficit to stimulate the demand for goods and labor. Because it was impossible for government to run both a surplus and a deficit at the same time, the net effect of this analysis in matters of public policy was paralysis—a paralysis punctuated by periodic attempts to stimulate or restrain the economy. These attempts were quicky abandoned for their alternatives. The disenchantment with Keynesian policies was intensified as inflation moved many Americans into higher tax brackets unaccompanied by comparable increases in purchasing power.

The essays in *The Crisis in Economic Theory* present a variety of theoretical formulations that might provide alternatives to the neoclassical synthesis as a basis for policy. To some, as in Mark Willes' exposition of rational expectations theory, the critical variable in economics consists of the expectations of individuals attempting to adapt to a highly uncertain future. Because no one knows in advance what will happen to the economy when government policy changes, there is a need for reducing uncertainties created by government policy by minimizing the government's economic role. Appropriately, Willes regards the rational expectations theory as constituting a "counterrevolution" in economics. Israel Kirzner's well-reasoned essay on the Austrian perspective in economics recommends a return to economists' earlier focus on the entrepreneur as the strategic factor in explaining the dynamics of the economy. Irving Kristol contends that current economic theory has retreated into a mode of overrefinement that obscures the critical substratum of truth in the classical and neoclassical emphasis on the importance of individual self-interest in promoting economic growth. The common thread in these essays is the absence of a role for government as an economic balance and a penchant for abandoning the Keynesian element in the neoclassical synthesis.

At the other end of the spectrum, the Neo-Keynesians, illustrated by Paul Davidson's essay, seek to provide the theoretical underpinning for a more active government role in the economy. The Neo-Keynesians appear to represent more of a tendency than a formalized theory, a tendency that would replace the neoclassical synthesis with a synethesis of the Keynesian emphasis on the government's role in stabilizing the economy with more activist government policies in controlling industry and lessening economic inequalities. A Marxist perspective, represented by Edward Nell's essay, contends that the Marxian theory of value and capital provides a valid framework for assessing the socioeconomic changes that have produced the present economic drift and for anticipating future directions. A common denominator of the critics represented in the volume is their vision of the economy as one dominated by giant firms possessing market power rather than by the competitive pressures assumed in the neoclassical theory.

Crisis in Economic Theory underscores the uneasy union that has typically existed between economic theory and labor economics. This union is likely to become more insecure if the Keynesian component in the neoclassical synthesis loses its significance for policy. The conventional neoclassical theory focuses on labor as a cost of production, and the theory tends to view labor organizations as semimonopolistic restraints in the labor market. Economists concerned with labor issues have tended to stress the importance of bargaining, group behavior, and social factors concerned with livelihood. Keynesian economics built in a positive role for labor organizations because of it emphasis on wages as income and purchasing power as well as costs. Union efforts to raise wages, therefore, could frequently be justified as benefiting society as well as union members because they helped to maintain high levels of effective demand. The differences in approach are also illustrated by the controversies over maintaining or increasing the statutory minimum wage. The minimum wage standards that protect livelihood and purchasing power in the view of most Keynesian-oriented labor economists are regarded in the neoclassical tradition as the cause for much of the recent severe unemployment among young people, especially young blacks.

In his essay on "Models and Reality in Economic Discourse," Daniel Bell cogently relates theoretical issues in economics to the substantive changes that have characterized the larger society. According to Bell, the contemporary economic models are losing their relevance in explaining reality, because the economies to which they refer have been transformed by technological advances, market power, and expansion of the Government's role in the economy. In democratic capitalist societies in which governments account for between 20 and 60 percent of all economic transactions, economic theories based on the behavior of atomistic individuals who are assumed to be maximizing their preferences provide limited insight. Economic choices take on a political dimension as they increasingly become influenced by the government's collective decisionmaking as in defense outlays, or by the efforts of organized groups made up of farmers, businessmen, wage earners, or older persons to seek the government's aid in protecting their economic status. Bell's critique raises anew the question presented 75 years ago by that acerbic and insightful critic of orthodox economic theory, Thorstein Veblen. Veblen asked, "Why is Economics Not an Evolutionary Science?" The absence of a significant response to Veblen's question helps to explain much of the predicament faced by economic theory in the 1970's and early 1980's.

STATEMENT OF OWNERSHIP, MANAGEMENT AND CIRCULATION
(Required by 39 U.S.C. 3685)

1. Title of Publication: Monthly Labor Review
2. Date of Filing: 10-19-82
3. Frequency of Issue: Monthly
4. Annual Subscription Price: $23
5. Location of Known Office of Publication: 441 G Street, N.W., Washington, D.C. 20212
6. Location of the Headquarters of General Business Offices of the Publishers: 441 G Street, N.W., Washington, D.C. 20212
7. Names and Complete Addresses of Publisher, Editor, and Executive Editor: Publisher: U.S. Department of Labor, Bureau of Labor Statistics, 441 G Street, N.W., Washington, D.C. 20212; Editor: Henry Lowenstern, same address; Executive Editor: Robert Fisher, same address
8. Owner: U.S. Department of Labor, Bureau of Labor Statistics, 441 G Street, N.W., Washington, D.C. 20212
9. Known Bondholders, Mortgagees, and Other Security Holders Owning or Holding 1 Percent or More of Total Amount of Bonds, Mortgages or Other Securities: None
10. Extent and Nature of Circulation:

	Average No. Copies Each Issue During Preceding 12 Months	*Actual No. of Copies of Single Issue Published Nearest To Filing Date*
A. Total number copies printed (net press run)	16,200	15,074
B. Paid circulation:		
1. Sales through dealers and carriers, street vendors, and counter sales	2,402	1,543
2. Mail subscriptions	11,618	11,618
C. Total paid circulation	14,020	13,161
D. Free distribution by mail, carrier, or other means (samples, complimentary, and other free copies)	1,980	1,763
E. Total distribution (sum of C and D)	16,000	14,924
F. Copies not distributed:		
1. Office use, leftover, unaccounted, spoiled after printing	200	150
2. Returns from news agents	NA	NA
G. Total (sum of E, F1 and 2—should equal net press run shown in A)	16,200	15,074

I certify that the statements made by me above are correct and complete.

33. Wage and compensation change, major collective bargaining settlements, 1977 to date 94
34. Effective wage adjustments in collective bargaining units covering 1,000 workers or more, 1977 to date 94

Work stoppage data. Definition 95
35. Work stoppages involving 1,000 workers or more, 1947 to date 95

NOTES ON CURRENT LABOR STATISTICS

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics. A brief introduction to each group of tables provides definitions, notes on the data, sources, and other material usually found in footnotes.

Readers who need additional information are invited to consult the BLS regional offices listed on the inside front cover of this issue of the *Review*. Some general notes applicable to several series are given below.

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might otherwise mask short-term movements of the statistical series. Tables containing these data are identified as "seasonally adjusted." Seasonal effects are estimated on the basis of past experience. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years.

Seasonally adjusted labor force data in tables 2–7 were revised in the March 1982 issue of the *Review* to reflect experience through 1981. The original estimates also were revised to 1970 to reflect 1980 census population controls.

Beginning in January 1980, the BLS introduced two major modifications in the seasonal adjustment methodology for labor force data. First, the data are being seasonally adjusted with a new procedure called X-11/ARIMA, which was developed at Statistics Canada as an extension of the standard X-11 method. A detailed description of the procedure appears in *The X-11 ARIMA Seasonal Adjustment Method* by Estela Bee Dagum (Statistics Canada Catalogue No. 12-564E, February 1980). The second change is that seasonal factors are now being calculated for use during the first 6 months of the year, rather than for the entire year, and then are calculated at mid-year for the July-December period. Revisions of historical data continue to be made only at the end of each calendar year.

Annual revision of the seasonally adjusted payroll data shown in tables 10, 12, and 14 were made in August 1981 using the X-11 ARIMA seasonal adjustment methodology. New seasonal factors for productivity data in tables 28 and 29 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month to month and from quarter to quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of $3 and a current price index number of 150, where 1967 = 100, the hourly rate expressed in 1967 dollars is $2 ($3/150 × 100 = $2). The resulting values are described as "real," "constant," or "1967" dollars.

Availability of information. Data that supplement the tables in this section are published by the Bureau of Labor Statistics in a variety of sources. Press releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule given below. The *BLS Handbook of Labor Statistics*, Bulletin 2070, provides more detailed data and greater historical coverage for most of the statistical series presented in the *Monthly Labor Review*. More information from the household and establishment surveys is provided in *Employment and Earnings*, a monthly publication of the Bureau. Historically, comparable information from the establishment survey is published in two comprehensive data books—*Employment and Earnings, United States* and *Employment and Earnings, States and Areas*, and their annual supplements. More detailed information on wages and other aspects of collective bargaining appears in the monthly periodical, *Current Wage Developments*. More detailed price information is published each month in the periodicals, the *CPI Detailed Report* and *Producer Prices and Price Indexes*.

Symbols

p = preliminary. To improve the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.
r = revised. Generally, this revision reflects the availability of later data but may also reflect other adjustments.
n.e.c. = not elsewhere classified.

Schedule of release dates for major BLS statistical series

Series	Release date	Period covered	Release date	Period covered	Release date	Period covered	MLR table number
Employment situation	November 5	October	December 3	November	January 7	December	1–10
Producer Price Index	November 16	October	December 10	November	January 14	December	21–25
Consumer Price Index	November 23	October	December 21	November	January 21	December	17–20
Real earnings	November 23	October	December 21	November	January 21	December	11–15
Productivity and costs:							
Nonfinancial corporations	November 29	3rd quarter	....	....	....	....	26–29
Nonfarm business and manufacturing	....	....	....	....	January 28	4th quarter	26–29
Major collective bargaining settlements	....	....	....	....	January 31	1982	33–34

EMPLOYMENT DATA FROM THE HOUSEHOLD SURVEY

EMPLOYMENT DATA in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 60,000 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons are (1) those who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work because they were on layoff or waiting to start new jobs within the next 30 days are also counted among the unemployed. The **unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **civilian labor force** consists of all employed or unemployed persons in the civilian noninstitutional population; the **total labor force** includes military personnel. Persons **not in the labor force** are those not classified as employed or unemployed; this group includes persons retired, those engaged in their own housework, those not working while attending school, those unable to work because of long-term illness, those discouraged from seeking work because of personal or job market factors, and those who are voluntarily idle. The **noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy.

Full-time workers are those employed at least 35 hours a week; **part-time workers** are those who work fewer hours. Workers on part-time schedules for economic reasons (such as slack work, terminating or starting a job during the week, material shortages, or inability to find full-time work) are among those counted as being on full-time status, under the assumption that they would be working full time if conditions permitted. The survey classifies unemployed persons in full-time or part-time status by their reported preferences for full-time or part-time work.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the preceding years. These adjustments affect the comparability of historical data presented in table 1. A description of these adjustments and their effect on the various data series appear in the Explanatory Notes of *Employment and Earnings*.

Data in tables 2–7 are seasonally adjusted, based on the seasonal experience through December 1981.

1. Employment status of the noninstitutional population, 16 years and over, selected years, 1950–81

[Numbers in thousands]

Year	Total noninstitutional population	Total labor force		Civilian labor force							Not in labor force
					Employed				Unemployed		
		Number	Percent of population	Total	Total	Percent of population	Agriculture	Nonagricultural industries	Number	Percent of labor force	
1950	106,645	63,858	59.9	62,208	58,918	55.2	7,160	51,758	3,288	5.3	42,787

EMPLOYMENT, HOURS, AND EARNINGS DATA FROM ESTABLISHMENT SURVEYS

EMPLOYMENT, HOURS, AND EARNINGS DATA in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by 177,000 establishments representing all industries except agriculture. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

Definitions

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in manufacturing include blue-collar worker supervisors and all nonsupervisory workers closely associated with production operations. Those workers mentioned in tables 11–15 include production workers in manufacturing and mining; construction workers in construction; and nonsupervisory workers in transportation and public utilities; in wholesale and retail trade; in finance, insurance, and real estate; and in services industries. These groups account for about four-fifths of the total employment on private nonagricultural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W). The **Hourly Earnings Index** is calculated from average hourly earnings data adjusted to exclude the effects of two types of changes that are unrelated to underlying wage-rate developments: fluctuations in overtime premiums in manufacturing (the only sector for which overtime data are available) and the effects of changes and seasonal factors in the proportion of workers in high-wage and low-wage industries.

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received and are different from standard or scheduled hours. **Overtime hours** represent the portion of gross average weekly hours which were in excess of regular hours and for which overtime premiums were paid.

Notes on the data

Establishment data collected by the Bureau of Labor Statistics are periodically adjusted to comprehensive counts of employment (called "benchmarks"). The latest complete adjustment was made with the release of May 1982 data, published in the July 1982 issue of the *Review*. Consequently, data published in the *Review* prior to that issue are not necessarily comparable to current data. Complete comparable historical unadjusted and seasonally adjusted data are published in a Supplement to Employment and Earnings (unadjusted data from April 1977 through February 1982 and seasonally adjusted data from January 1974 through February 1982) and in *Employment and Earnings, United States, 1909–78*, BLS Bulletin 1312–11 (for prior periods).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20. See also *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976).

NOTE: The industry divisions of mining; construction; tobacco manufactures (a major manufacturing group, nondurable goods); transportation and public utilities; and finance, insurance, and real estate are no longer shown. This is because the seasonal component in these is small relative to the trend-cycle, or irregular components, or both, and consequently cannot be precisely separated.

p=preliminary.

UNEMPLOYMENT INSURANCE DATA

NATIONAL UNEMPLOYMENT INSURANCE DATA are compiled monthly by the Employment and Training Administration of the U.S. Department of Labor from monthly reports of unemployment insurance activity prepared by State agencies. Railroad unemployment insurance data are prepared by the U.S. Railroad Retirement Board.

Definitions

Data for **all programs** represent an unduplicated count of insured unemployment under State programs, Unemployment Compensation for Ex-Servicemen, and Unemployment Compensation for Federal Employees, and the Railroad Insurance Act.

Under both State and Federal unemployment insurance programs for civilian employees, insured workers must report the completion of at least 1 week of unemployment before they are defined as unemployed. Persons not covered by unemployment insurance (about 10 percent of the labor force) and those who have exhausted or not yet earned benefit rights are excluded from the scope of the survey. **Initial claims** are notices filed by persons in unemployment insurance programs to indicate they are out of work and wish to begin receiving compensation. A claimant who continued to be unemployed a full week is then counted in the insured unemployment figure. The **rate of insured unemployment** expresses the number of insured unemployed as a percent of the average insured employment in a 12-month period.

An **application** for benefits is filed by a railroad worker at the beginning of his first period of unemployment in a benefit year; no application is required for subsequent periods in the same year. **Number of payments** are payments made in 14-day registration periods. The **average amount of benefit payment** is an average for all compensable periods, not adjusted for recovery of overpayments or settlement of underpayments. However, **total benefits paid** have been adjusted.

[1] Initial claims and State insured unemployment include data under the program for Puerto Rican sugarcane workers.

[2] Excludes transition claims under State programs.

[3] Excludes data on claims and payments made jointly with other programs.

[4] Excludes data on claims and payments made jointly with State programs.

[5] Cumulative total for fiscal year (October 1-September 30). Data computed quarterly.

NOTE: Data for Puerto Rico and the Virgin Islands included. Dashes indicate data not available.

r = revised.

p = preliminary.

PRICE DATA

PRICE DATA are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period (1967 = 100, unless otherwise noted).

Definitions

The **Consumer Price Index** is a monthly statistical measure of the average change in prices in a fixed market basket of goods and services. Effective with the January 1978 index, the Bureau of Labor Statistics began publishing CPI's for two groups of the population. One index, a new CPI for All Urban Consumers, covers 80 percent of the total noninstitutional population; and the other index, a revised CPI for Urban Wage Earners and Clerical Workers, covers about half the new index population. The All Urban Consumers index includes, in addition to wage earners and clerical workers, professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctor's and dentist's fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items is kept essentially unchanged between major revisions so that only price changes will be measured. Prices are collected from over 18,000 tenants, 24,000 retail establishments, and 18,000 housing units for property taxes in 85 urban areas across the country. All taxes directly associated with the purchase and use of items are included in the index. Because the CPI's are based on the expenditures of two population groups in 1972–73, they may not accurately reflect the experience of individual families and single persons with different buying habits.

Though the CPI is often called the "Cost-of-Living Index," it measures only price change, which is just one of several important factors affecting living costs. Area indexes do not measure differences in the level of prices among cities. They only measure the average change in prices for each area since the base period.

Producer Price Indexes measure average changes in prices received in primary markets of the United States by producers of commodities in all stages of processing. The sample used for calculating these indexes contains about 2,800 commodities and about 10,000 quotations per month selected to represent the movement of prices of all commodities produced in the manufacturing, agriculture, forestry, fishing, mining, gas and electricity, and public utilities sectors. The universe includes all commodities produced or imported for sale in commercial transactions in primary markets in the United States.

Producer Price Indexes can be organized by stage of processing or by commodity. The stage of processing structure organizes products by degree of fabrication (that is, finished goods, intermediate or semifinished goods, and crude materials). The commodity structure organizes products by similarity of end-use or material composition.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States, from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

In calculating Producer Price Indexes, price changes for the various commodities are averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1972. The detailed data are aggregated to obtain indexes for stage of processing groupings, commodity groupings, durability of product groupings, and a number of special composite groupings.

Price indexes for the output of selected SIC industries measure average price changes in commodities produced by particular industries, as defined in the *Standard Industrial Classification Manual 1972* (Washington, U.S. Office of Management and Budget, 1972). These indexes are derived from several price series, combined to match the economic activity of the specified industry and weighted by the value of shipments in the industry. They use data from comprehensive industrial censuses conducted by the U.S. Bureau of the Census and the U.S. Department of Agriculture.

Notes on the data

Beginning with the May 1978 issue of the *Review*, regional CPI's cross classified by population size, were introduced. These indexes will enable users in local areas for which an index is not published to get a better approximation of the CPI for their area by using the appropriate population size class measure for their region. The cross-classified indexes will be published bimonthly. (See table 19.)

For further details about the new and the revised indexes and a comparison of various aspects of these indexes with the old unrevised CPI, see *Facts About the Revised Consumer Price Index*, a pamphlet in the Consumer Price Index Revision 1978 series. See also *The Consumer Price Index: Concepts and Content Over the Years*, Report 517, revised edition (Bureau of Labor Statistics, May 1978).

For interarea comparisons of living costs at three hypothetical standards of living, see the family budget data published in the *Handbook of Labor Statistics, 1977*, Bulletin 1966 (Bureau of Labor Statistics, 1977), tables 122–133. Additional data and analysis on price changes are provided in the *CPI Detailed Report* and *Producer Prices and Price Indexes*, both monthly publications of the Bureau.

As of January 1976, the Wholesale Price Index (as it was then called) incorporated a revised weighting structure reflecting 1972 values of shipments. From January 1967 through December 1975, 1963 values of shipments were used as weights.

For a discussion of the general method of computing consumer, producer, and industry price indexes, see *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976), chapters 13–15. See also John F. Early, "Improving the measurement of producer price change," *Monthly Labor Review*, April 1978, pp. 7–15. For industry prices, see also Bennett R. Moss, "Industry and Sector Price Indexes," *Monthly Labor Review*, August 1965, pp. 974–82.

[1] Data for May 1982 have been revised to reflect the availability of late reports and corrections by respondents. All data are subject to revision 4 months after original publication.

[2] Prices for natural gas are lagged 1 month.

[3] Includes only domestic production.

[4] Most prices for refined petroleum products are lagged 1 month.

[5] Some prices for industrial chemicals are lagged 1 month.

r = revised.

r = revised.

PRODUCTIVITY DATA

PRODUCTIVITY DATA are compiled by the Bureau of Labor Statistics from establishment data and from estimates of compensation and output supplied by the U.S. Department of Commerce and the Federal Reserve Board.

Definitions

Output is the constant dollar gross domestic product produced in a given period. Indexes of **output per hour of labor input,** or labor productivity, measure the value of goods and services produced per hour of labor. **Compensation per hour** includes wages and salaries of employees plus employers' contributions for social insurance and private benefit plans. The data also include an estimate of wages, salaries, and supplementary payments for the self-employed, except for nonfinancial corporations, in which there are no self-employed. **Real compensation per hour** is compensation per hour adjusted by the Consumer Price Index for All Urban Consumers.

Unit labor cost measures the labor compensation cost required to produce one unit of output and is derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from the current dollar gross domestic product and dividing by output. In these tables, **unit nonlabor costs** contain all the components of unit nonlabor payments except unit profits. **Unit profits** include corporate profits and inventory valuation adjustments per unit of output.

The **implicit price deflator** is derived by dividing the current dollar estimate of gross product by the constant dollar estimate, making the deflator, in effect, a price index for gross product of the sector reported.

The use of the term "man hours" to identify the labor component of productivity and costs, in tables 26 through 29, has been discontinued. **Hours of all persons** is now used to describe the labor input of payroll workers, self-employed persons, and unpaid family workers. **Output per all-employee** hour is now used to describe labor productivity in nonfinancial corporations where there are no self-employed.

Notes on the data

In the business sector and the nonfarm business sector, the basis for the output measure employed in the computation of output per hour is Gross Domestic Product rather than Gross National Product. Computation of hours includes estimates of nonfarm and farm proprietor hours.

Output data are supplied by the Bureau of Economic Analysis, U.S. Department of Commerce, and the Federal Reserve Board. Quarterly manufacturing output indexes are adjusted by the Bureau of Labor Statistics to annual estimates of output (gross product originating) from the Bureau of Economic Analysis. Compensation and hours data are from the Bureau of Economic Analysis and the Bureau of Labor Statistics.

Beginning with the September 1982 issue of the *Review*, all of the productivity and cost measures contained in these tables are based on revised output and compensation measures released by the Bureau of Economic Analysis in July as part of the regular revision cycle of the National Income and Product Accounts. Measures of labor input have been revised to reflect results of the 1980 census, and seasonal factors have been recomputed for use in the preparation of quarterly measures. The word "private" is no longer being used as part of the series title of one of the two business sector measures prepared by BLS; no change has been made in the definition or content of the measures as a result of this change.

WAGE AND COMPENSATION DATA

DATA FOR THE EMPLOYMENT COST INDEX are reported to the Bureau of Labor Statistics by a sample of 2,000 private nonfarm establishments and 750 State and local government units selected to represent total employment in those sectors. On average, each reporting unit provides wage and compensation information on five well-specified occupations.

Data on negotiated wage and benefit changes are obtained from contracts on file at the Bureau, direct contact with the parties, and secondary sources.

Definitions

The **Employment Cost Index** (ECI) is a quarterly measure of the average change in the cost of employing labor. The rate of total compensation, which comprises wages, salaries, and employer costs for employee benefits, is collected for workers performing specified tasks. Employment in each occupation is held constant over time for all series produced in the ECI, except those by region, bargaining status, and area. As a consequence, only changes in compensation are measured. Industry and occupational employment data from the 1970 Census of Population are used in deriving constant weights for the ECI. While holding total industry and occupational employment fixed, in the estimation of indexes by region, bargaining status, and area, the employment in those measures is allowed to vary over time in accord with changes in the sample. The rate of change (in percent) is available for wages and salaries, as well as for total compensation. Data are collected for the pay period including the 12th day of the survey months of March, June, September, and December. The statistics are neither annualized nor adjusted for seasonal influence.

Wages and salaries consist of earnings before payroll deductions, excluding premium pay for overtime, work on weekends and holidays, and shift differentials. Production bonuses, incentive earnings, commissions, and cost-of-living adjustments are included; nonproduction bonuses are included with other supplemental pay items in the benefits category; and payments-in-kind, free room and board, and tips are excluded. *Benefits* include supplemental pay, insurance, retirement and savings plans, and hours-related and legally required benefits.

Data on negotiated wage changes apply to private nonfarm industry collective bargaining agreements covering 1,000 workers or more. Data on compensation changes apply only to those agreements covering 5,000 workers or more. *First-year* wage or compensation changes refer to average negotiated changes for workers covered by settlements reached in the period and implemented within the first 12 months after the effective date of the agreement. *Changes over the life of the agreement* refer to all adjustments specified in the contract, expressed as an average annual rate. These measures exclude wage changes that may occur under cost-of-living adjustment clauses, that are triggered by movements in the Consumer Price Index. *Wage-rate changes* are expressed as a percent of straight-time hourly earnings; *compensation changes* are expressed as a percent of total wages and benefits.

Effective wage adjustments reflect all negotiated changes implemented in the reference period, regardless of the settlement date. They include changes from settlements reached during the period, changes deferred from contracts negotiated in an earlier period, and cost-of-living adjustments. The data also reflect contracts providing for no wage adjustment in the period. Effective adjustments and each of their components are prorated over all workers in bargaining units with at least 1,000 workers.

Notes on the data

The Employment Cost Index data series began in the fourth quarter of 1975, with the quarterly percent change in wages and salaries in the private nonfarm sector. Data on employer costs for employee benefits were included in 1980, to produce a measure of the percent change in employers' cost for employees' total compensation. State and local government units were added to the ECI coverage in 1981, providing a measure of total compensation change in the civilian nonfarm economy.

Data for the broad white-collar, blue-collar, and service worker groups, and the manufacturing, nonmanufacturing, and service industry groups are presented in the ECI. Additional occupation and industry detail are provided for the wages and salaries component of total compensation in the private nonfarm sector. For State and local government units, additional industry detail is shown for both total compensation and its wages and salaries component.

Historical indexes (June 1981 = 100) of the quarterly rates of changes presented in the ECI are also available.

For a more detailed discussion of the ECI, see chapter 25, "The Employment Cost Index," of the BLS *Handbook of Methods* (Bulletin 1910), and the *Monthly Labor Review* articles: "Employment Cost Index: a measure of change in the 'price of labor,'" July 1975; "How benefits will be incorporated into the Employment Cost Index," January 1978; and "The Employment Cost Index: recent trends and expansion," May 1982.

Additional data for the ECI and other measures of wage and compensation changes appear in *Current Wage Developments*, a monthly periodical of the Bureau.

[1] The total number of workers who received adjustments does not equal the sum of workers that received each type of adjustment, because some workers received more than one type of adjustment during the period.

p=preliminary.

WORK STOPPAGE DATA

WORK STOPPAGES include all known strikes or lockouts involving 1,000 workers or more and lasting a full shift or longer. Data are based largely on newspaper accounts and cover all workers idle one shift or more in establishments directly involved in a stoppage. They do not measure the indirect or secondary effect on other establishments whose employees are idle owing to material or service shortages.

Estimates of days idle as a percent of estimated working time measures only the impact of larger strikes (1,000 workers or more). Formerly, these estimates measured the impact of strikes involving 6 workers or more; that is, the impact of virtually *all* strikes. Due to budget stringencies, collection of data on strikes involving 6 workers or more was discontinued with the December 1981 data.

35. Work stoppages involving 1,000 workers or more, 1947 to date

Month and year	Number of stoppages: Beginning in month or year	Number of stoppages: In effect during month or year	Workers involved: Beginning in month or year (in thousands)	Workers involved: In effect during month (in thousands)	Days idle: Number (in thousands)	Days idle: Percent of estimated working time

SALES PUBLICATIONS

BLS Bulletins

Analyzing 1981 Earnings Data From the Current Population Survey. Bulletin 2149, 27 pp., $3.75 (GPO Stock No. 029-001-02715-0). A reprint of two April 1982 Monthly Labor Review articles—Usual weekly earnings: another look at intergroup differences and basic trends; and Earnings of men and women: a look at specific occupations.

Back Injuries Associated With Lifting. Bulletin 2144, 20 pp., $3.50 (GPO Stock No. 029-001-02712-5). Summarizes the results of a survey of workers in blue-collar occupations who injured their backs while lifting, placing, lowering, carrying, or holding objects.

Unemployment and Its Effect on Family Income in 1980. Bulletin 2148, 36 pp., $4.50 (GPO Stock No. 029-001-02713-3). An April 1982 Monthly Labor Review reprint which shows that the median income of families with an unemployed member was 21 percent lower than that of families without unemployment.

Area Wage Survey Bulletins

These bulletins cover office, professional, technical, maintenance, custodial, and material movement occupations in major metropolitan areas. The annual series of 70 is available by subscription for $90 per year. Individual area bulletins are also available separately. The following were published in September:

Cincinnati, Ohio-Kentucky-Indiana, Metropolitan Area, July 1982. Bulletin 3015-32, 53 pp., $4.75 (GPO Stock No. 029-001-90152-6).

Corpus Christi, Texas, Metropolitan Area, July 1982. Bulletin 3015-28, 39 pp., $4.50 (GPO Stock No. 029-001-90148-8).

Daytona Beach, Florida, Metropolitan Area, August 1982. Bulletin 3015-36, 34 pp., $4.50 (GPO Stock No. 029-001-90156-9).

Green Bay, Wisconsin, Metropolitan Area, August 1982. Bulletin 3015-33, 25 pp., $3.50 (GPO Stock No. 029-001-90153-4).

Norfolk-Virginia Beach-Portsmouth, Virginia-North Carolina, Metropolitan Area, May 1982. Bulletin 3015-29, 40 pp., $4.50 (GPO Stock No. 029-001-90149-6).

Norfolk-Virginia Beach-Portsmouth and Newport News-Hampton, Virginia-North Carolina, Metropolitan Area, May 1982. Bulletin 3015-30, 40 pp., $4.50 (GPO Stock No. 029-001-90150-0).

Oklahoma City, Oklahoma, Metropolitan Area, August 1982. Bulletin 3015-35, 27 pp., $3.50 (GPO Stock No. 029-001-90155-1).

Portland, Oregon-Washington, Metropolitan Area, June 1982. Bulletin 3015-31, 32 pp., $3.75 (GPO Stock No. 029-001-90151-8).

Providence-Warwick-Pawtucket, Rhode Island-Massachusetts, Metropolitan Area, June 1982. Bulletin 3015-34, 50 pp., $4.75 (GPO Stock No. 029-001-90154-2).

South Bend, Indiana, August 1982. Bulletin 3015-37, 40 pp., $4.50 (GPO Stock No. 029-001-90157-7).

Periodicals

CPI Detailed Report. July issue provides a comprehensive report on price movements for the month, questions and answers on upcoming changes in the measurement of homeownership costs, statistical tables, charts, and technical notes. 81 pp., $3.50 ($20 per year).

Current Wage Developments. August issue includes employee wage and benefit changes and collective bargaining settlements in July and a special report on collective bargaining settlements in the private sector during the first 6 months of 1982. 60 pp. September issue includes employee wage and benefit changes and collective bargaining settlements in August and special reports on State and local government collective bargaining settlements during the first 6 months of 1982 and on the Employment Cost Index for June of 1982. 56 pp., $2.50 ($14 per year).

Employment and Earnings. September issue covers employment and unemployment developments in August, plus regular statistical tables on national, State, and area employment, unemployment, hours, and earnings. 124 pp., $3.75 ($31 per year).

Occupational Outlook Quarterly. Fall issue features articles on industrial robots, emerging occupations, the shortage of machinists, the accuracy of BLS' 1970-80 projections, manufacturing engineering, and comparing occupations using four factors—size, projected rate of growth, average earnings, and susceptibility to unemployment. 32 pp., $2.75 ($8 per year).

Producer Prices and Price Indexes. July issue includes a comprehensive report on price movements for the month, and provides information on the addition of data from the Producer Price Index revision program, changes in presentation of detailed product price indexes, availability of computer tape for Producer Price Index revision data, and phase-out of the industry sector price indexes, plus regular charts, text, tables, and technical notes. 130 pp., $3.25 ($20 per year).

Supplement to Producer Prices and Price Indexes: Data for 1981. Presents monthly indexes and annual averages for 1981, information on relative importance of index components at the end of the year, historical annual indexes for selected stage-of-processing groupings, rebased historical indexes for bituminous coal by region, and 1981 indexes for the newly introduced postal services series. 169 pp., $3.50 (included in $20 subscription price for Producer Prices and Price Indexes).

U.S. Department of State Indexes of Living Costs Abroad, Quarters Allowances, and Hardship Differentials. Tabulations computed quarterly by the Allowances Staff of the Department of State for use in establishing allowances to compensate American civilian government employees for costs and hardships related to assignments abroad. The information is also used by many business firms and private organizations to assist in establishing private compensation systems. Report 670. 8 pp., $1.75 ($6.50 per year).

PRODUCTIVITY AT HOME AND ABROAD

Patricia Capdevielle and others 3 **International trends in productivity and labor costs**
Productivity in manufacturing generally rose, unit labor cost trends moderated in U.S. and 10 other countries in 1981; relative productivity and labor cost indexes introduced

Arthur S. Herman 15 **Productivity increased in 1981 in most industries measured**
Although productivity growth slowed during 1976–81 for most of the industries surveyed, a majority of significant industries showed advances in output per employee hour in 1981

Horst Brand, John Duke 19 **Productivity in banking: computers spur the advance**
Nevertheless, the trend in output per employee hour paralleled that of the economy between 1967 and 1980, with the annual rate of growth decelerating after 1973

Patricia A. Wilder 28 **Cosmetics industry achieves long-term productivity gains**
But recent declines have beset an industry in which productivity has grown rapidly since 1958; with gains linked in part to more efficient plants, and improved technology

J. Edwin Henneberger 33 **The office furniture industry: patterns in productivity**
Product proliferation and short production runs limited the use of laborsaving equipment in factories; as a result, productivity advanced only moderately between 1958 and 1980

Horst Brand, Clyde Huffstutler 38 **Productivity in the pump and compressor industry**
During 1958–80, the industry experienced long-term advances, reflecting improvements in metalworking machinery and computer aid; increases have decelerated since 1965

Labor Month In Review

JOB SAFETY. The Bureau of Labor Statistics reported results of its annual survey of job-related injuries and illnesses. The data, collected during 1982, show that occupational injuries and illnesses declined in 1981. The all-industry incidence rate was 8.3 injuries and illnesses per 100 full-time workers, compared with 8.7 in 1980.

The latest survey shows that the numbers of injuries and illnesses both with and without loss of worktime declined in the private sector. Because the number of employees on the job and the hours they worked changed little between 1980 and 1981, the injuries and illnesses rate also declined.

In 1981, there were 4,370 work-related deaths in units employing 11 workers or more, compared with 4,400 in 1980. The corresponding fatality rate was essentially unchanged—7.6 per 100,000 workers in 1981 versus 7.7 in 1980.

Release of the 1981 survey results marks the 10th full year of data collection under the Occupational Safety and Health Act of 1970. Over these years, during which employment expanded by about 15 million, injuries declined from about 1 in every 10 workers in 1972 to 1 in every 13 in 1981. The rate for lost-time injuries, which rose between 1972 and 1979, declined in the last 2 years; however, the rate of injuries without loss of worktime has fallen steadily over the 10-year period.

Occupational injuries. Work-related injuries occurred at a rate of 8.1 per 100 full-time workers during 1981—down from 8.5 in 1980.

Among industry divisions, increases in the injury incidence rates occurred in the agriculture, forestry, and fishing industries and in mining. Finance, insurance, and real estate and retail trade showed no change, and the injury rate fell in construction, manufacturing, transportation and public utilities, wholesale trade, and services. The rate for establishments in construction, which is the highest of all industry divisions, declined from 15.5 in 1980 to 14.9 in 1981. In manufacturing, the rate declined from 11.8 to 11.1 The lowest rate (1.9) occurred in finance, insurance, and real estate.

The incidence rate of injuries involving lost workdays declined in 5 of the 9 industry divisions. While establishments in the agriculture, forestry, and fishing division showed a small increase, finance, insurance, and real estate, retail trade, and services showed no change in the rate.

Of the 72 major industry groups, incidence rates decreased in 50, increased in 14, and remained unchanged in 8. Incidence rates for injuries involving lost workdays decreased in 43, increased in 16, and were unchanged in 13 of the 72 industries.

The severity of injuries is reflected in the incidence rate of lost workdays. In 1981, there were 60.4 lost workdays per 100 full-time workers—down from 63.7 in 1980. The lost workdays incidence rate in mining continues to be the highest among all industry divisions and has been more than twice the national average since 1977. But because the number of lost workdays associated with each injury in mining declined, the lost workdays rate declined, from 162.8 in 1980 to 145.7 in 1981, the largest drop in any industry division.

The injury incidence rate fell from 1980 to 1981 in all employment-size groups, except for establishments with 50 to 99 employees, which showed no change. As in previous years, rates in establishments with fewer than 50 workers or with 1,000 workers or more were lower than mid-size establishment rates. Rates continued to be highest in the 100-to-249-employee size firms. Only in the manufacturing division did the incidence rate drop for each size category.

Occupational illnesses. Occupational illnesses include any abnormal condition or disorder, other than one resulting from an occupational injury, caused by exposure to environmental factors associated with employment. The incidence of occupational illnesses measured by the annual survey refers to the number of new illness cases occurring during a year and does not measure continuing conditions of illness reported in previous surveys. Illnesses are recorded only for the year in which they are recognized and diagnosed as work-related.

From both statistical and procedural points of view, occupational illness estimates generated from the annual survey provide a valid measure of recognized acute cases. However, current statistics do not adequately reflect that portion of occupational illnesses which are chronic or long-latent because of problems of detection and recognition.

About 126,100 occupational illnesses were recognized in 1981; the number recognized in 1980 was 130,200. In both years, illnesses accounted for only 2.3 percent of total injuries and illnesses. Skin diseases or disorders continued to account for the majority of all illnesses—about 4 of every 10 cases. This is largely because they are easier to recognize and diagnose than other diseases.

Background of survey. The Annual Survey of Occupational Injuries and Illnesses is a Federal/State cooperative program in which State agencies participate with the Bureau of Labor Statistics of the U.S. Department of Labor. Response to the 1981 survey was mandatory. The sample consisted of approximately 280,000 units in the private sector. The occupational injury and illness data reported through the annual survey are based on the records which employers maintain under the Occupational Safety and Health Act of 1970.

TABLES SHOWING THE survey results appear in the news release, USDL 82-423, available from the Inquiries and Correspondence Section, Bureau of Labor Statistics, Washington, D.C. 20212. A BLS bulletin with full survey details is in preparation. □

International trends in productivity and labor costs

Output per employee hour in manufacturing generally improved and unit labor cost trends moderated in the U.S. and 10 other nations in 1981; relative productivity and labor cost indexes are introduced

PATRICIA CAPDEVIELLE, DONATO ALVAREZ,
AND BRIAN COOPER

Manufacturing productivity increased in 1981 in the United States, Japan, and most European countries studied, with gains ranging from about 2 to 4 percent in the United States, Japan, France, Germany,[1] Italy, and the Netherlands, to almost 6 percent in the United Kingdom and Denmark, and more than 7 percent in Belgium. In Canada and Sweden, productivity remained essentially unchanged.

These productivity changes occurred in what was for most countries the second year of recession. In most European countries, productivity rose because employment and hours declined more than output. In the United States, Canada, and Japan, productivity gains were accompanied by modest output growth—temporary recoveries from 1980 declines in the United States and Canada.

Unit labor cost increases, which reflect changes in both productivity and hourly compensation costs, ranged from 2 to 5 percent in Japan, Germany, Belgium, Denmark, and the Netherlands, up to 15 percent in France and 18 percent in Italy. When measured in U.S. dollars, however, unit labor costs declined substantially in all the European countries—5 to 20 percent—because of the sharp appreciation of the dollar, while rising 7 to 8 percent in Canada and Japan as well as in the United States.

While the 1981 appreciation of the dollar partially offset the lower long-term U.S. cost trend, unit labor costs in the United States nevertheless declined 29 percent between 1970 and 1981, relative to the average costs of our trade competitors. Unit labor costs in Canada, Belgium, Denmark, the Netherlands, and Italy also declined relative to those of their trade competitors while those of Japan, France, Germany, the United Kingdom, and Sweden increased.

This article describes developments in manufacturing productivity (as measured by output per hour), hourly compensation, and unit labor costs in 1981, and compares the 1980–81 trends with those of the 1974–75 recession, for the United States, Canada, Japan, France, Germany, Italy, the United Kingdom, and four smaller European countries—Belgium, Denmark, the Netherlands, and Sweden.[2] Percent changes in productivity, labor costs, and related measures for selected periods and for each year from 1973 are shown in tables 1 through 3;[3] percent changes are also presented for the eight European countries and for the 10 foreign countries combined.[4] (Annual indexes for the years 1950 to 1981 are available from the authors.) The data for 1981 are based on preliminary underlying statistics, while those for other recent years reflect revised underlying statistics for several countries.

Although the productivity measure relates output to the hours of persons employed in manufacturing, it does not measure the specific contributions of labor as a single factor of production. Rather, it reflects the joint effects of many influences, including new technology,

Patricia Capdevielle, Donato Alvarez, and Brian Cooper are economists in the Division of Foreign Labor Statistics and Trade, Bureau of Labor Statistics.

capital investment, the level of output, capacity utilization, energy use, and managerial effectiveness, as well as the skills and efforts of the work force.

This article also introduces new measures of relative trends in productivity and labor costs. Table 5 presents indexes of relative output per hour, hourly compensation, and unit labor costs in national currency and in U.S. dollars for the 11 countries. Each relative index represents the ratio of a country's own index to a weighted geometric average of the corresponding indexes for the other 10 countries; the weights used to combine the other country indexes reflect the relative importance of each country as a manufacturing trade competitor (table 4).

Productivity trends

In 1981, manufacturing productivity increased by more than 7 percent in Belgium, almost 6 percent in the United Kingdom and Denmark, and about 2 to 4 percent in the United States, Japan, France, Germany, Italy, and the Netherlands. In Canada and Sweden, it rose less than 0.5 percent. (See table 1.)

For the United States, the 1981 productivity gain was the largest annual increase since 1976. And for Belgium and the United Kingdom, the 1981 gains were the largest in many years. For Japan and Italy, the 1981 increases represent substantial slowdowns from large 1980 gains, but for most other countries, they were improvements over small gains or productivity declines in the previous year.

Output. With the exception of a small gain in Denmark, manufacturing output fell in each of the European countries in 1981—by more than 6 percent in the United Kingdom and about 1 to 4 percent in the other countries. In the non-Scandinavian countries, productivity increased because employment and hours declined even more than output. Most of Denmark's productivity gain also resulted from decreases in employment and hours. In Sweden, hours and output fell equally.

The 1981 drop in British output followed an even larger 1980 decline of 9 percent. For France and Belgium, 1981 marked the second consecutive year of declining output, but the 1980 declines were under 1 percent. Germany, Denmark, Sweden, and the Netherlands had zero or only slight 1980 output increases—under 1 percent—while Italy had a more substantial gain. In most countries, output turned down during the first half of 1980, and showed little if any recovery by late 1981 or early 1982. Only in Italy did output recover in late 1980 and turn down again in 1981.

In the United States and Canada, 1980 manufacturing output levels declined about 3 to 4 percent from previous year levels, but 1981 annual output levels were up 2 percent. In both countries, manufacturing production dropped in the second quarter of 1980, recovered in the fourth quarter, then turned down again during the second half of 1981. In Japan, manufacturing output increased more than 9 percent in 1980, and rose another 3 percent in 1981, but then turned down during the first half of 1982.

Table 1. Annual percent changes in manufacturing productivity and output, 11 countries, 1960–81

Year	United States	Canada	Japan	France	Germany	Italy	United Kingdom	Belgium	Denmark	Netherlands	Sweden	Eight European countries	Ten foreign countries

NOTE: Rates of change computed from the least squares trend of the logarithms of the index numbers.

Employment and hours. Manufacturing employment and aggregate hours both increased only in Canada in 1981; in Japan, employment rose slightly but total hours were essentially unchanged. In 1980, hours had increased slightly in Canada and by more than 2 percent in Japan. In the United States, employment and hours declined only slightly in 1981, after falling more than 3 percent in 1980. (See table 2.)

In Europe, employment declined 10 percent in the United Kingdom and 2 to 6 percent in the other countries in 1981. Those declines followed 1980 drops of 6 percent in the United Kingdom and 1 to 2 percent in most of the other countries. Employment had increased slightly in Germany in 1980 and was essentially unchanged in Italy and Sweden. Aggregate hours fell even more than employment in 1981—except in Denmark—as average hours were also reduced.

Comparisons with 1974–75. Comparisons of developments during the years 1980 and 1981 with the recession of 1974–75 cannot be precise, particularly when dealing with annual average data, because of differences among countries in the extent and timing of the 1974–75 recession and the 1980–81 downturns. Nevertheless, certain broad comparisons can be made.

Over the 1974–75 period, manufacturing output fell in one or both years in all 11 countries studied. During 1980–81, neither Japan nor Denmark experienced annual average declines in output, although Denmark had virtually no output growth over the period and Japanese output slowed sharply in 1981; most of the other countries had smaller output declines than in 1974–75. However, there were exceptions. The recent output declines in the United Kingdom were substantially greater than during 1974–75, and those in France and Sweden also appear to have been larger. Only in the United States did output regain its pre-1974 average rate of growth during the 1976–79 recovery period.

As in the case of output, manufacturing employment and hours declined less sharply during 1980–81 than during 1974–75 in most of the countries studied. For example, German employment declined about 2 percent in 1980–81, compared with 9 percent in 1974–75, and total hours declined 5 percent versus 15 percent. Again, major exceptions were France, where employment and hours declined somewhat more in 1980–81, and the United Kingdom, where the recent declines—16 percent for employment and 21 percent for total hours—were substantially greater than those in 1974–75. In Sweden, the employment effects of the 1974–75 recession were delayed; therefore, direct comparison between the two periods is not appropriate.

Although employment losses over the 2-year period of 1980–81 were less severe in most countries than in 1974–75, employment in most of Europe also declined during the intervening 1976–79 period. The rate of decline ranged from about 1 percent per year in France and Germany to almost 4 percent annually in Belgium. Only in Denmark and Italy was employment essentially stable during the recovery period. By 1981, employment in manufacturing was down 6, 11, and 14 percent from 1973 levels in Sweden, France, and Germany; 17 percent in Denmark and the Netherlands; and almost 25 percent in Belgium and the United Kingdom. In contrast, employment in the United States and Canada was higher in 1981 than in 1973.

All European countries have taken actions, through collective bargaining or government programs, to shorten average hours worked to preserve manufacturing jobs. Most countries have partial unemployment benefit programs to provide wage replacement to employees on short work schedules for economic reasons. In addition, minimum annual holiday (vacation) entitlements have been increased in Denmark, Germany, the Netherlands, Sweden, and the United Kingdom (and are scheduled to increase in France) as a job creation measure as well as a fringe benefit improvement. (In Italy, on the other hand, several national holidays were abolished in 1977 as a labor cost cutting measure, although many employees receive extra annual holidays in lieu of the national holidays.) In Belgium, the standard workweek was shortened through collective bargaining from 40 hours in 1977 to 38 hours for most employees in 1981; the shorter hours are provided as either a shorter workweek or a longer annual holiday.

Given the relative output and employee-hours changes, manufacturing productivity increased in most countries during both the 1974–75 recession and in 1980–81. The following tabulation shows average annual productivity changes over the two periods:

	1974–75	*1980–81*
United States	0.2	1.5
Canada	–.2	–1.5
Japan	3.2	5.0
France	3.3	1.6
Germany	5.4	2.1
Italy	.2	4.6
United Kingdom	–.6	3.2
Belgium	5.1	5.2
Denmark	6.8	3.5
Netherlands	3.2	2.2
Sweden	1.6	.7

In the United States, Japan, Italy, and the United Kingdom, the productivity trend was higher during 1980–81, while productivity gains were higher during 1974–75 in France, Germany, Denmark, the Netherlands, and Sweden. In Belgium, productivity rose equally in both periods. In Canada, productivity declined in both periods.

Hourly compensation

Hourly compensation increases in 1981 varied considerably among the 11 countries studied. The

NOTE: Rates of change computed from the least squares trend of the logarithms of the index numbers.

smallest gain was 5 percent in the Netherlands and the largest, 22 percent in Italy. In the United Kingdom and France, the increases were also large—over 16 percent. In Japan and Germany, the gains were relatively small—under 8 percent—while in the United States, Canada, Belgium, Denmark, and Sweden, they were 9 to 12 percent. (See table 3.)

Four countries—the United States, Germany, Denmark, and the United Kingdom—showed some degree of moderation in hourly compensation gains for 1981. In the United Kingdom, there was a substantial slowdown from the 24 percent recorded in 1980. (In the Netherlands, a significant slowdown occurred in 1980.) In Canada, Japan, Italy, and Sweden, however, the 1981 increases were higher than those of the previous year, and in France, Belgium, and the Netherlands, the increases in both years were virtually tbe same.

Compared with the hourly compensation trend during the 1974–75 recession, annual rates of increase during the 1980–81 period were considerably lower in every country except the United States and France. In the United States, however, the 1974–75 increases were relatively small. The moderation in wage gains and other labor costs occurred even though consumer price trends were generally about as high in 1980–81 as in 1974–75—with Japan and Belgium as principal exceptions. However, growing concern with moderating labor costs and containing inflation, as well as preserving manufacturing jobs, had a significant impact on recent compensation trends.

Concerted action was taken in several countries to moderate wage settlements during 1980–81. Temporary pay freezes were imposed in Belgium and the Netherlands and a temporary price freeze was undertaken in Sweden. The Dutch government subsequently imposed statutory pay controls. In several countries with wage indexation systems, the price indexes used were adjusted to exclude fuel and energy prices, or the cost-of-living allowances (COLA's) normally payable were reduced or rescinded.

In Japan and Germany, annual wage agreements in 1980 and 1981 continued the moderate pattern of recent years. In Japan, the average manufacturing settlement was 6.7 percent in 1980 and 7.6 percent in 1981, and in Germany, the average settlements were 6.7 percent in 1980 and 4.6 percent in 1981. In the United States and the United Kingdom, wage-and-salary concessions were made in some impacted companies or industries.

In the Netherlands, a pay freeze was imposed from January through April 1980, followed by statutory controls which were later extended through 1981. No basic wage increases were allowed. Furthermore, the June 1980 cost-of-living adjustment was restricted to a flat-rate amount, and the January 1981 adjustment was reduced by 2 percent. In 1981, holiday bonuses were lowered slightly, and extra annual holidays delayed.

The Belgian Government imposed a pay freeze in January 1981. The national wage agreement signed in February, under threat of statutory pay controls, provided either a 1-percent wage rate increase or an extra hour off the standard workweek by 1983. Wages are indexed for consumer price increases in Belgium, however, and the indexation system was not changed. The emphases of recent wage settlements in Belgium have not been basic wage increases but reductions of standard hours. Standard weekly hours were reduced from 40 hours per week in 1977 to 38 hours for most workers by 1980, and the 1981 national agreement allowed additional reductions. Because wage rates are adjusted to compensate for the shorter workweek, the hours reductions are measured as hourly compensation gains.

Wage rates are also indexed for consumer price increases in Italy, and cost-of-living allowances are paid under collective agreements in Denmark, Sweden, and the United Kingdom. In Italy as in Belgium, the indexation system continued unchanged during 1980–81. In Denmark and Sweden, COLA payments were restricted. In Denmark, the index used to compute the COLA's was changed in December 1979 to exclude fuel and energy prices, and was also rebased. As a result, one of the COLA's was eliminated in 1980. In Sweden, the 1981 pay agreements specified exclusion of energy prices from the consumer price index used in COLA computation. The government imposed a price freeze in September 1981 and cut value-added taxes in November, and thereby kept the price rise below the COLA threshold (trigger) specified in the pay agreement.

In Denmark, early 1981 wage settlements at the industry level provided moderate wage increases and restricted additional company-level wage negotiations. In

France, there were no government restrictions on wage increases during 1980–81, and wage rate increases followed the consumer price index although there is no formal indexation system. Minimum-wage increases above the price index rate raised average wages further in some lower wage industries. In Italy, the major wage agreements were concluded in 1979 and expired in late 1981. Their wage rate provisions and the indexation system were not limited, although there were discussions of labor cost reductions and indexation changes for 1982. In Italy and several other European countries, actions were taken to cut employers' social security tax rates, although in other cases tax rates were raised to finance system deficits.

Unit labor costs

Unit labor costs, which reflect the interplay between hourly compensation and output per hour, increased about 7 percent in the United States and 10 to 12 percent in Canada, Sweden, and the United Kingdom in 1981, compared with more than 14 percent in France and 18 percent in Italy, but only 2 to 5 percent in Denmark, Japan, Germany, Belgium, and the Netherlands. (See table 3.)

In every country except Japan, France, Italy, and Sweden, unit labor costs increased less in 1981 than in the previous year. In the United Kingdom, the slowdown from the 23 percent recorded in 1980 was substantial, and reflected both a smaller compensation increase and a larger productivity gain. In most other countries also, the moderation in unit labor costs reflects a slowdown in hourly compensation and improvements in productivity. In France, the 1981 increase in unit labor costs, as well as in productivity and hourly compensation, was essentially the same as the previous year's. In Japan and Italy, the acceleration in unit labor costs primarily reflects their productivity slowdowns.

The 1980–81 increases in unit labor costs were generally much smaller than those of 1974–75 because hourly compensation gains were relatively moderate, in contrast to the substantial wage gains during the 1974–75 recession. The average annual unit labor cost increases for the two periods are shown in the following tabulation:

	1974–75	*1980–81*
United States	11.0	9.4
Canada	15.2	11.8
Japan	20.3	1.9
France	15.5	14.7
Germany	7.9	5.9
Italy	26.8	15.2
United Kingdom	28.3	16.3
Belgium	16.0	4.2
Denmark	12.5	6.4
Netherlands	13.2	2.9
Sweden	17.6	10.9

For some countries—Japan, Belgium, Denmark, and the Netherlands—the differences are substantial. Even for the countries with the largest unit labor cost increases in 1980–81—Italy and the United Kingdom—the recent increases are down considerably from 1974–75 peaks. The differences are less marked for the United States and Germany, which had the smallest 1974–75 unit labor cost increases.

In U.S. dollars. In comparing trends in unit labor costs among countries, an important analytical element is the shift in relative currency values through international exchange rate adjustments. In recent years, the number and extent of such adjustments have been so great as to constitute a major variable in competitive assessment.

The relationship between exchange rate shifts and unit labor cost trends is partial and indirect but nonetheless important. The two are linked by the price mechanism, a main determinant of trade directions and competitive relationships. Because labor cost is the principal cost factor in the production of manufactured goods, it exerts a strong influence on the price at which goods can be offered in international markets. Relative changes in exchange rates alter the effect of relative changes in costs in national currency. Consequently, in assessing relative changes in unit labor costs in competitive terms, changes in exchange rates need to be taken into account.

Changes in currency exchange rates in 1981 had a significant effect on relative changes in unit labor costs measured in U.S. dollars. The dollar appreciated substantially—from about 15 percent to more than 30 percent—relative to the European currencies. (By September 1982, the dollar had further appreciated—compared with the annual average for 1981—10 percent versus the German mark and Dutch guilder, and 8 to 30 percent versus the other European currencies.) The dollar also appreciated somewhat relative to the Canadian dollar, but declined slightly versus the Japanese yen. (By September 1982, however, the dollar had appreciated 19 percent versus the yen, as well as another 3 percent versus the Canadian dollar.)

Therefore, when measured in U.S. dollars, unit labor costs in the European countries fell about 5 percent in Sweden and the United Kingdom; 11 percent in France and Italy; 16 percent in Germany; and 18 to 20 percent in Belgium, the Netherlands, and Denmark. In U.S. dollars, unit labor costs increased 8 percent in Canada and 7 percent in Japan—about the same rate as for U.S. costs. (See table 3.)

The largest contrast was between Japan and Germany. On a national currency basis, they had increases of 4 and 5 percent, respectively. On a U.S. dollar basis, Japanese unit labor costs rose 7 percent while German unit labor costs fell 16 percent.

While the 5-percent decline in the United Kingdom was not as large as in the other European countries, it was the sharpest trend reversal among all the countries, for British unit labor costs had increased 35 percent in 1980. Unit labor costs in Japan had posted a small decline in 1980; among the other countries, they had risen 2 to 16 percent.

The trend in unit labor costs in U.S. dollars for the 1980–81 period differs significantly from that for the years 1974–75 in most countries covered. First, unit labor costs in national currency increased much less during 1980–1981 in most countries. Secondly, the U.S. dollar appreciated versus all European currencies and the Canadian dollar in 1981, while in 1974–75, the dollar appreciated versus the Japanese yen, Italian lira, and British pound but depreciated versus all the other currencies. Therefore, unit labor costs in U.S. dollars increased substantially more in most other countries than in the United States during the 1974–75 recession, while in the 1980–81 period, unit labor costs in U.S. dollars declined in all European countries covered.

Relative productivity and cost trends

Indexes of manufacturing productivity and labor costs are often used in analyses of changes in the relative competitive position of countries in the international trade of manufactures. Unit labor costs are an important element in determining the underlying price competitiveness of manufactured products, with relative productivity and hourly compensation trends determining unit labor cost performance. The International Monetary Fund (IMF) and Organization for Economic Cooperation and Development (OECD) publish indexes for key cost and price measures—including unit labor costs in U.S. dollars—which show the trend of each country's own indicators relative to those of other industrial (competitor) countries.[5] The BLS unit labor cost measures are used in the computation of the IMF and OECD indicators for most countries they cover. The following section introduces indexes of trade-weighted relative trends in manufacturing productivity, hourly compensation, and unit labor costs in national currency, as well as unit labor costs in U.S. dollars.

Because trade involves individual products, the use of aggregate manufacturing measures as indicators of trade competitiveness has certain limitations. In general, labor productivity growth rates in export sectors probably exceed those for manufacturing as a whole. On the other hand, hourly compensation tends to grow at similar rates in all manufacturing sectors within a country. Overall, therefore, trend measures for the total manufacturing sector would be expected to overstate, to some extent, the growth of unit labor costs for the export sector. However, this would probably be true for every country, and, in any case, the measures are intended to represent relative changes only. In addition, exchange rate changes have a significant effect on relative unit labor cost developments, and these affect unit labor costs in all manufacturing industries equally.

Index calculation methods. The indexes of relative trends in manufacturing productivity and labor costs represent ratios of each country's own indexes to weighted geometric averages of the corresponding indexes for the other 10 "competitor" countries.

The weights used to combine the other 10 countries' indexes into an average "competitors" index reflect the relative importance of each country as a manufacturing trade competitor. The weights are those developed by the IMF for computation of their own relative cost and price indicators—except that they have been adjusted from the 14-country coverage of the IMF series to the 11-country coverage of the BLS series.[6] The weights are based on disaggregated trade data for manufacturers in 1975. They take into account the relative importance of each country's trading partners in its direct bilateral trade with them and the relative importance of those partners in competition in "third country" markets, ad-

Table 4. Trade weights used to compute competitor indexes

NOTE: Because of rounding, sums of individual items may not equal 100.0.

justed for the importance of foreign trade to the manufacturing sector as a whole in each country.[7] Table 4 shows the weights used for each of the 11 countries.

The relative indexes of output per hour, hourly compensation, and unit labor costs in national currency and in U.S. dollars are shown in table 5. The underlying "own country" and "competitor countries" indexes used to compute the relative indexes, and indexes of trade-weighted exchange rates, not shown in table 5, are available from the authors.

Chart 1 shows the trends from 1970 to 1981 in U.S. manufacturing output per hour, hourly compensation, and unit labor costs compared with those for its trade-weighted competitors, as well as relative U.S. versus competitors trends. Charts 2 and 3 show the relative unit labor cost trends in national currency and in U.S. dollars for four countries—the United States, Japan, Germany, and the United Kingdom; the three foreign countries shown are important U.S. trade partners, and each also represents different relative cost trends.

Relative productivity trends. The countries in which manufacturing productivity grew more rapidly than that of trade competitors since 1970 were Japan, Belgium,

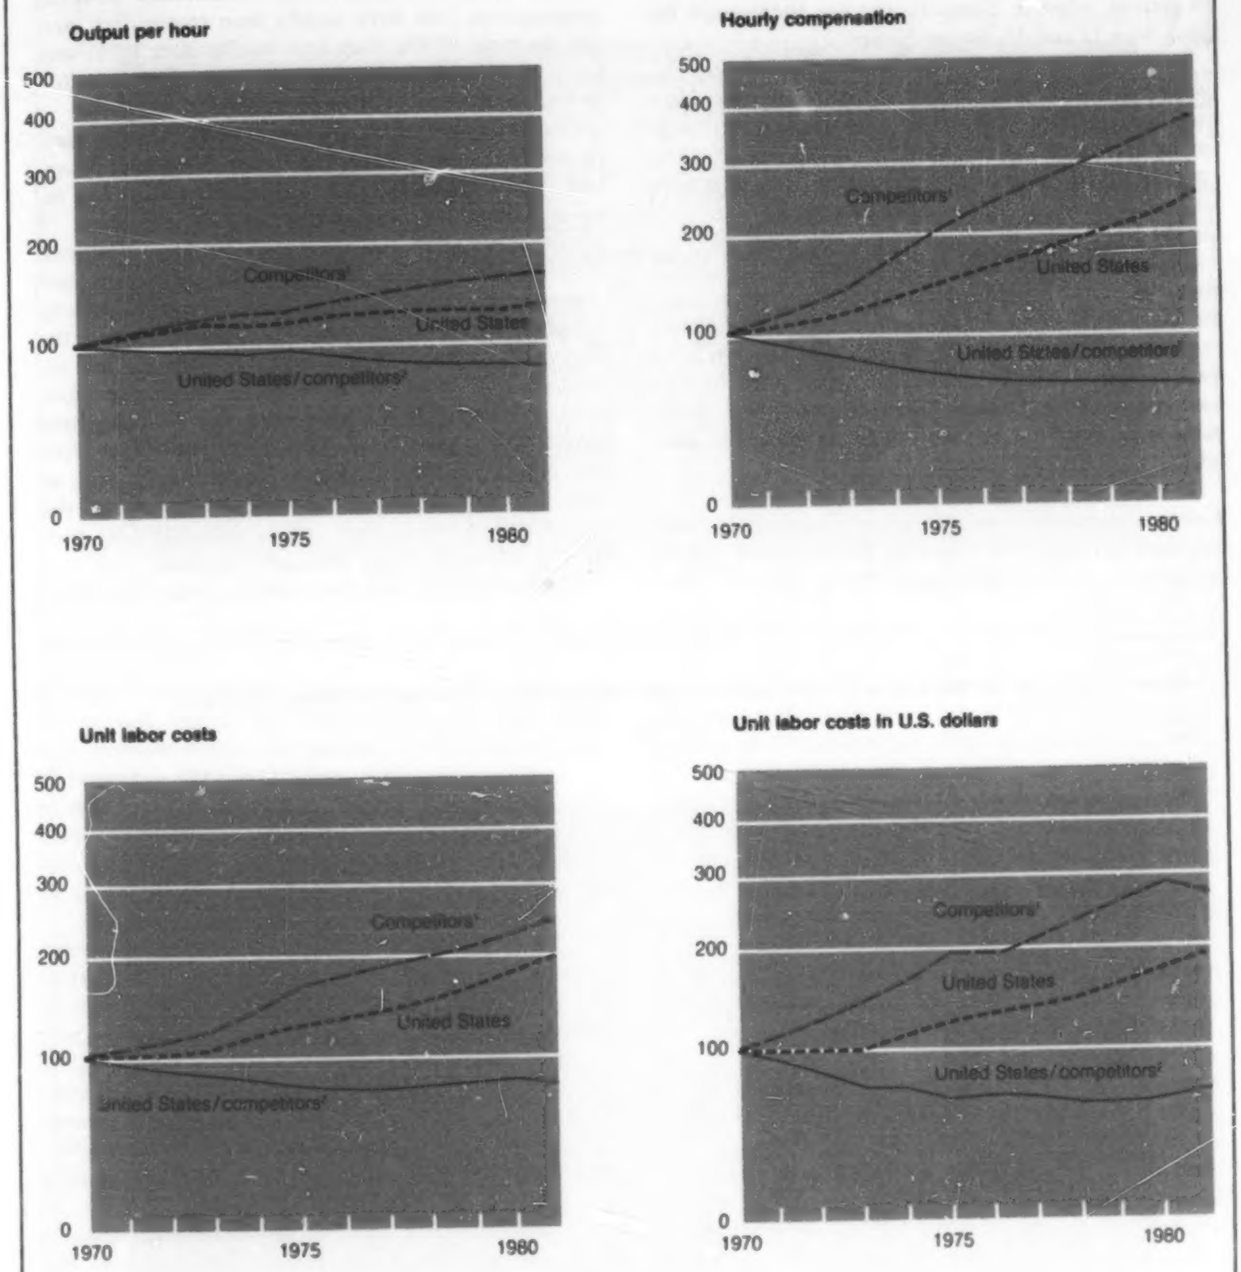
Note: Relative indexes are calculated from the ratio of the reference country index to a trade-weighted average index for the other 10 countries.

Chart 1. U.S. productivity and labor costs relative to 10 competitor countries, 1970-81

[1970=100]



[1] Weighted geometric average of the indexes for 10 competitor countries.

[2] Relative index calculated from the ratio of the U.S. index to the competitors' index.

the Netherlands, and Denmark. Productivity had risen 11 to 12 percent more in Denmark and the Netherlands and 16 percent more in Japan and Belgium by 1976. By 1981, their relative trends had diverged: For Japan, productivity gains were 41 percent higher and for Belgium, 29 percent, while in Denmark and the Netherlands the gains were 12 and 13 percent higher.

In France, Germany, and Italy, productivity increased at about the same rate as that of trade competitors from 1970 to 1981. Their relative rates of change varied during the period, however. In the early 1970's, productivity in France and Germany rose somewhat less rapidly, and in Italy it rose more rapidly, but during the late 1970's, the relative rates were reversed.

Productivity rose less rapidly than in competitor countries for the United States, Canada, Sweden, and the United Kingdom. From 1970 to 1981, U.S. relative productivity had increased 19 percent less, while in Sweden and the United Kingdom, gains were 13 percent lower, and in Canada, 7 percent lower. The slower gains were quite consistent throughout the entire period.

Relative compensation trends. Hourly compensation rose less than in competitor countries in the United States, Germany, and the Netherlands. From 1970 to 1981, compensation increased about 35 percent less in the United States, 30 percent less in Germany, and 10 percent less in the Netherlands. For the United States and Germany, the slower relative trend was fairly consistent over the whole period. For the Netherlands, however, compensation rose more rapidly than competitors' during the early 1970's, then less rapidly after 1976, with the greatest relative declines occurring in 1980–81, following the imposition of wage controls.

Hourly compensation rose more rapidly than in competitor countries in Italy, the United Kingdom, Japan, and France. From 1970 to 1981, compensation had increased about 100 percent more in Italy and about 75 percent more in the United Kingdom. Almost without exception, both had consistently larger gains than their competitors throughout the 1970–81 period. Hourly compensation in Japan rose more rapidly during the early 1970's—by 1975, Japanese compensation had increased about 35 percent more than that of competitors—but grew less rapidly after 1975. By 1981, Japanese compensation gains were only 8 percent higher than competitors'. In France, hourly compensation rose at about the same rate as in competitor countries until the mid-1970's, then rose more rapidly to end in 1981 with about a 20-percent larger cumulative increase.

Canada, Belgium, and Denmark also ended the 1970–

Chart 2. Relative indexes of unit labor costs in national currency, selected countries, 1970-81

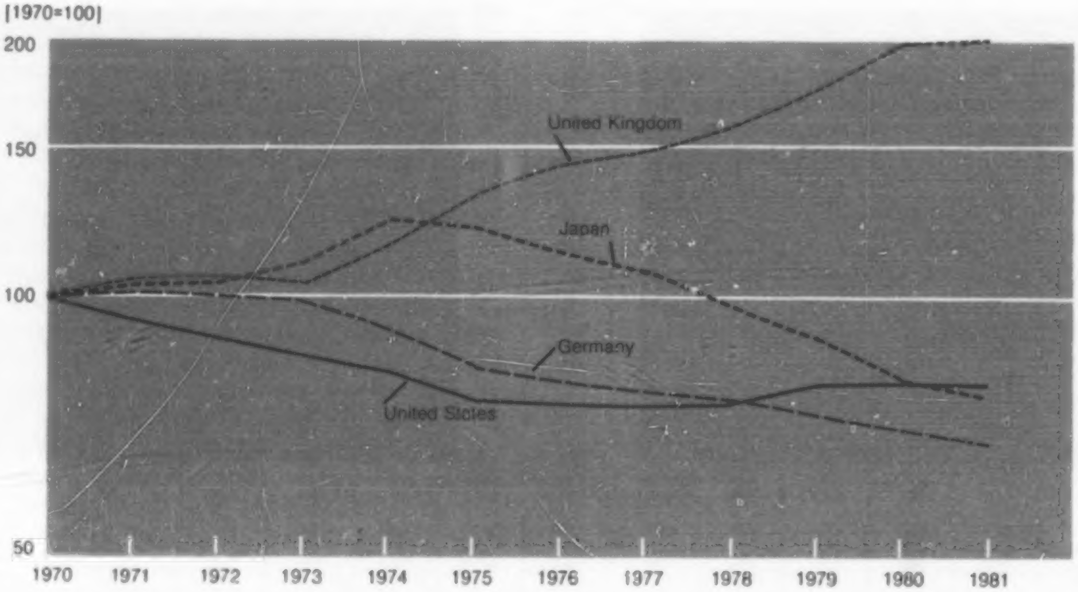


Chart 3. Relative indexes of unit labor costs in U.S. dollars, selected countries, 1970-81

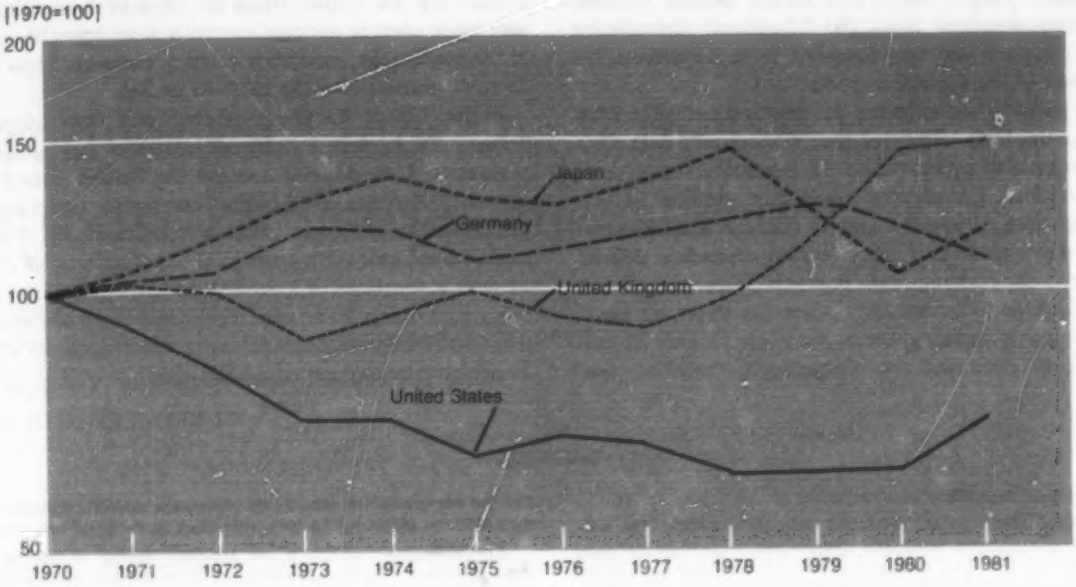

81 period with somewhat larger compensation increases. But in each country, the 1981 relative gains were down from previous peaks—in Canada, 6 percent down from 10 percent in 1977; in Belgium, 5 percent down from 16 percent in 1976–77; and in Denmark, 6 percent down from 9 percent in 1974–79. In Sweden, hourly compensation generally rose at about the same rate as competitor countries' over the 1970–81 period.

Relative unit labor cost trends. Unit labor costs in national currency increased less from 1970 to 1981 in six countries—the United States, Japan, Germany, Belgium, Denmark, and the Netherlands—than in their competitor countries. The relative trend was 6 percent lower in Denmark by 1981, and about 20 to 30 percent lower in the other countries.

The relative change for the United States was down because hourly compensation had fallen more than output per hour. In Japan, Belgium, and Denmark, relative productivity gains more than offset relative compensation increases; in Germany, the relative productivity trend was about level, but relative compensation was sharply down; and the Netherlands had both productivity and hourly compensation advantages.

The relative trend for the United States was steadily downward from 1970 to 1977, up moderately from 1977 to 1980, and down again slightly in 1981. Relative unit labor costs in Japan rose over 20 percent more than those of competitors by 1974–75, then declined steadily to 23 percent less than competitors' by 1981. Relative unit labor costs declined steadily in Germany from 1973, in Belgium and the Netherlands from 1975, and in Denmark from 1979. For the Netherlands, the most significant relative cost declines occurred during 1980 and 1981.

Unit labor costs in national currency increased by at least 100 percent more than competitors' in Italy and the United Kingdom and by about 15 to 20 percent more in Canada, France, and Sweden. The large relative increases in Italy and the United Kingdom are attributable to hourly compensation gains as the relative productivity trend was down in the United Kingdom and essentially level in Italy. In Canada and France, hourly compensation was up slightly, and the productivity trend was down in Canada and even in France. In Sweden, hourly compensation trends were equal to those of competitors, but productivity fell from 1970 relative levels.

In U.S. dollars. After adjustment for the relative change in the foreign exchange rate of the dollar, U.S. unit labor costs showed a decline of nearly 30 percent versus those of competitors from 1970 to 1981, compared with about 20 percent in national currency. In 1980, relative unit labor costs adjusted for the dollar exchange rate were down almost 40 percent. However, the U.S. dollar appreciated 10 percent against trade-weighted U.S. competitor currencies from 1980 to 1981. This primarily reflected the dollar's appreciation relative to the German mark, French franc, and British pound, because, on a trade-weighted basis, the 2.5-percent appreciation of the Japanese yen was balanced by a 2.5-percent depreciation of the Canadian dollar.

Unit labor costs adjusted for relative exchange rates for Canada, Italy, Belgium, the Netherlands, and Denmark were also down—5 to 12 percent—versus competitors. For Canada, a 16-percent decline in the exchange rate, primarily against the U.S. dollar, offset higher increases in unit labor costs in Canadian dollars. For Italy, the exchange rate posted a 55-percent decline versus U.S. and German currencies. On the other hand, trade-weighted exchange rates were up 13 and 20 percent for Belgium and the Netherlands; therefore, relative unit labor costs in dollars declined less than in national currency terms.

For Germany and Japan, unit labor costs in U.S. dollars increased 8 and 19 percent more than those of trade competitors (principally the United States for Japan, and France and the United States for Germany) even though unit labor costs in national currency were down about 25 to 30 percent, because their relative exchange rates rose 55 to 60 percent over the 1970–81 period.

In the United Kingdom, relative unit labor costs increased 100 percent in national currency terms, but 46 percent in U.S. dollars, because the British pound declined 28 percent overall against competitor currencies—primarily the dollar and the German mark. In France and Sweden, unit labor costs in U.S. dollars posted 1970–81 relative increases of 7 percent, as costs in national currency rose nearly 20 percent more than those of competitors, but trade-weighted exchange rates declined about 10 percent versus competitor currencies. ☐

FOOTNOTES

[1] The Federal Republic plus West Berlin.

[2] The data relate to all employed persons, including the self-employed, in the United States and Canada, and to all wage and salary employees in the other countries. Hours refer to hours paid in the United States, hours worked in the other countries.

Compensation includes all payments made by employers directly to their employees (before deductions), plus employer contributions to legally required insurance programs and to contractual and private welfare plans for the benefit of employees. Labor costs include, in addition to compensation, employer expenditures for recruitment and training; the cost of cafeterias, medical facilities, and other plant facilities and services; and taxes (other than social security taxes, which are part of compensation) levied on payrolls or employment rolls. Annual data are not available for total labor costs. As used in this article, labor costs approximate more closely the concept of compensation. However, compensation has been adjusted to include all significant changes in taxes that are regarded as labor costs. For the United States and Canada, compensation of self-employed workers is measured by assuming that their hourly compensation is equal to the average for wage and salary employees.

[3] Percent changes for 1960–81, 1960–73, and 1973–81 shown in the tables are computed using the least squares method—that is, from the least squares trend of the logarithms of index numbers—in order to remove much of the effect of cyclical changes on the average rates of change, and thereby estimate the underlying trends.

[4] To compute the series for the eight European countries and 10 foreign countries, the data have been combined by aggregating the output, compensation, and hours figures for each year, adjusting where necessary for compatibility of coverage and concept. Average exchange rates for 1974–81 were used to aggregate the output and compensation data. The use of 1974–81 exchange rates, however, does not imply that these rates reflect the comparative real value of currencies for manufacturing output. Moreover, the use of exchange rates for a different period would have little effect on the combined series.

[5] The IMF publishes annual and quarterly indexes of relative unit labor costs and relative normalized unit labor costs in manufacturing—as well as relative value-added deflators, relative wholesale prices, and relative export unit values in manufacturing—for 14 industrial countries, in their monthly statistical publication *International Financial Statistics*. The OECD publishes quarterly indexes in chart form of relative unit labor costs in manufacturing, relative export unit values (prices) for manufactures, and relative consumer prices for 15 industrial countries in their monthly statistical publication *Main Economic Indicators*.

Series descriptions, data sources, and compilation methods for the IMF measures are described in "Intercountry Cost and Price Comparisons," a paper by Michael C. Deppler, Research Department, International Monetary Fund (November 1979); the OECD measures are described in *The International Competitiveness of Selected OECD Countries*, OECD Economic Outlook Occasional Studies, July 1978.

[6] The IMF weights were derived from disaggregated 5-digit Standard International Trade Classification data (up to 1,400 individual commodity classes) for each of the 14 countries covered by their series. The IMF weights have been simply adjusted to the 11-country BLS comparative series by eliminating the weights for the three uncovered countries—Austria, Norway, and Switzerland—and proportionately increasing the weights for the remaining 11 countries so that they equal 100 percent. The result should be little different from a comprehensive reweighting based on trade data for the 11 countries alone, because the omitted countries account for no more than 8.1 percent of the total 14-country weight for any of the 11 countries, and for a total of only 4 percent in the case of the United States.

[7] The weighting system is described in detail in Deppler, "Intercountry Cost and Price Comparisous."

Productivity increased in 1981 in most industries measured

Although productivity growth slowed during 1976–81 for most measured industries, a majority of significant industries show productivity gains in 1981

ARTHUR S. HERMAN

Productivity, as measured by output per employee hour, increased in 1981 in more than half of the industries for which the Bureau of Labor Statistics regularly publishes data. The growth in industry productivity was consistent with the gain in the nonfarm business sector of the economy, which grew 1.4 percent. In 1980, however, productivity declined in a majority of the measured industries.

Table 1 shows productivity trends in industries measured by the Bureau and includes measures for additional industries: millwork, office furniture (including separate measures for wood office furniture and metal office furniture), cosmetics, hand and edge tools, farm and garden machinery (including separate measures for farm machinery and equipment, and lawn and garden equipment), pumps and compressors (including separate measures for pumps and pumping equipment and air and gas compressors), and commercial banking.[1]

Changes by industry

Manufacturing. The steel industry, one of the more economically significant industries covered, gained 9.0 percent in productivity after two consecutive annual declines. This industry had a very good first half in 1981, buoyed by strong sales to the oil and gas industry. Despite a falloff in demand from many steel markets in the second half, output was up 9.8 percent while hours grew only 0.7 percent, leading to the significant productivity advance. Motor vehicle manufacturing, another key industry, had a notable gain in productivity of 4.7 percent in 1981 after three consecutive declines. Output was up 5.9 percent and hours grew 1.2 percent, as compared to a very poor previous year, when output fell 27.2 percent.

In tire manufacturing, productivity was up 13.3 percent. Output had a large gain of 8.6 percent, sustained by demand from the replacement market, while hours continued declining (−4.2 percent) in 1981. Many old and inefficient tire plants were closed in 1980, aiding the sharp productivity gain in 1981. Other large manufacturing industries with productivity increases included synthetic fibers (6.3 percent), gray iron foundries (5.9 percent), machine tools (4.6 percent), soft drinks (2.9 percent), corrugated and solid fiber boxes (2.7 percent), and pulp and paper (2.0 percent). All of these industries, except machine tools, experienced output growth in 1981.

Productivity declines were also recorded in a number of manufacturing industries in 1981. Many of these were construction related, such as construction machinery, brick and structural clay tile, and hydraulic cement. Output was down in these industries as overall construction activity continued to fall off during the year. Among other manufacturing industries with declining productivity, large drops were recorded by steel foundries (−5.5 percent), sugar (−5.2 percent), aluminum rolling and drawing (−4.0 percent), footwear (−3.6 percent), and folding paperboard boxes (−3.3 percent).

Arthur S. Herman is an economist in the Office of Productivity and Technology, Bureau of Labor Statistics.

[1] As defined in the *1972 Standard Industrial Classification Manual* published by the Office of Management and Budget.

[2] Preliminary.

[3] Not available.

[4] Percent change 1976-80.

[5] Output per employee.

[6] Output per hour of all persons.

NOTE: Although the output per employee hour measures relate output to the hours of all employees engaged in each industry, they do not measure the specific contribution of labor, capital, or any other single factor of production. Rather, they reflect the joint effects of many influences, including new technology, capital investment, the level of output, capacity utilization, energy use, and managerial skills, as well as the skills and efforts of the work force. Some of these measures use a labor input series that is based on hours paid and some use a labor input series that is based on plant hours.

N.E.C. = Not elsewhere classified.

Mining. All the mining industries measured experienced productivity gains in 1981. Coal mining posted its second consecutive large gain, growing 9.2 percent. Although coal output was down slightly (–1.3 percent) from the previous year, hours continued to decline sharply, resulting in the productivity gain. Productivity advances in the other mining industries were not as great as for coal. Iron mining (usable ore) rose 6.7 percent, copper mining (recoverable metal) increased 5.5 percent, and nonmetallic minerals gained 1.7 percent. Both copper and iron mining had large output increases in contrast to sharp declines in 1980. The productivity gain in nonmetallic minerals, however, was based on a drop in output, because of poor demand from the construction industry, and an even larger decline in hours.

Transportation and utilities. Productivity changes varied among transportation and utility industries. In railroads (revenue traffic), productivity gained 5.2 percent. Output in the railroad industry declined for the second straight year, dropping 0.7 percent, while hours continued to fall by 5.6 percent. Although output in the trucking industry fell 4.9 percent, employment dropped even more, resulting in a 4.7-percent productivity gain.

By contrast, productivity fell 0.3 percent in air transportation, as output continued to decline, by 2.8 percent, while employment dropped 2.5 percent.

In telephone communications, productivity was up 5.4 percent as output grew 5.6 percent. However, productivity fell in both gas (−3.8 percent) and electric utilities (−0.7 percent). Output was down in gas utilities, as many consumers curtailed usage because of rising prices, while hours increased owing to the growing number of customers. Output was up only 0.8 percent in electric utilities, well below the long-term rate of 6.6 percent, while hours grew 1.6 percent, resulting in the productivity falloff. Productivity dropped sharply (−8.3 percent) in petroleum pipelines as output fell for the second consecutive year because of declining demand for petroleum products, while hours increased.

Trade and services. Productivity changes also were varied among trade and service industries. Productivity grew 1.5 percent in retail food stores, as output was up 1.9 percent and hours grew 0.4 percent. New-car dealer productivity was up 1.4 percent. Gasoline service station productivity rose 1.2 percent. Output was down 2.1 percent in this industry, as demand was off because of increased gasoline prices and higher mileage cars, while hours fell even more, as marginal stations were closed and self-service stations became more prevalent. Productivity declined 1.9 percent in both eating and drinking places and hotels and motels, as small gains in output were compensated for by larger gains in hours. In drug stores, productivity fell 2.7 percent as output declined 1.9 percent and hours were up slightly. In the laundry and cleaning industry, productivity fell 3.2 percent because of a continued decline in demand for the industry's services which resulted in a 7.2-percent decrease in output, while hours fell 4.2 percent.

Trends, 1976–81

With the exception of the metal forming machine tools industry, all of the measured industries recorded gains over the long term (generally 1947–81 or 1958–81). Over the more recent period, 1976–81, a large number of the industries had declining productivity rates. In addition, about three-quarters of the industries had lower productivity during 1976–81 than over the preceding long-term period (1947–76 or 1958–76). This slowdown in productivity is consistent with the trends in the nonfarm business sector of the economy, where productivity increased at a rate of only 0.1 percent during 1976–81, compared with 2.3-percent growth from 1947–76.

Gains. In recent years the wet corn milling industry had the highest rate of productivity increase, growing 10.3 percent per year from 1976 to 1980 (1981 data are not yet available). Output in this industry grew at the high rate of 8.6 percent, as demand for high-fructose syrup, one of the industry's major products, continued to expand. At the same time, the industry continued to build new plants utilizing highly automatic equipment and hours declined at a rate of 1.6 percent.

The second highest rate of gain was recorded by the ceramic wall and floor tile industry, in which productivity grew at a rate of 7.4 percent from 1976 to 1980. Output increased 9.2 percent, while hours grew 1.7 percent. A new technique for firing tile became widespread, which, coupled with changes in materials handling, resulted in significant labor savings. The wood office furniture industry recorded a productivity gain averaging 7.0 percent during 1976–80. Output grew at the very high rate of 19.3 percent, as demand shifted from metal to wood office furniture, while hours grew at a rate of 11.5 percent.

Other industries with high rates of gain included synthetic fibers and fluid milk, both 6.2 percent from 1976 to 1981, and telephone communications, with 5.8-percent growth over the same period.

Declines. Among the many industries posting declining productivity from 1976 to 1981, the brick and structural clay tile industry had the largest average falloff, down 5.7 percent. Output dropped at a rate of 7.1 percent, because of declining demand from the construction industry, while hours fell 1.5 percent. Other industries with significant declines over this period included cosmetics (−3.4 percent during 1976–80), laundries (−3.2 percent), hydraulic cement (−2.5 percent), and clay construction products and petroleum pipelines (both −2.2 percent).

A full report, *Productivity Measures for Selected Industries, 1954–81*, BLS Bulletin 2155, is available from the Superintendent of Documents, U.S. Government Printing Office, Washington, D. C. 20402. ☐

Productivity in commercial banking: computers spur the advance

Nevertheless, output per employee hour paralleled the trend of the economy during 1967–80, with the annual rate of growth decelerating after 1973

HORST BRAND AND JOHN DUKE

The computer was among the major forces that spurred labor productivity advance in commercial banking in 1967–80. The computer also facilitated great increases in banking output. Labor requirements per unit of output, however, declined rather slowly during the period.

Output per employee hour in commercial banking rose at an average annual rate of 1.3 percent between 1967 and 1980—nearly the same as for the nonfarm business sector as whole (1.4 percent).[1] Data for a productivity measure for years prior to 1967 are inadequate, and none was calculated. Output over the period examined rose at a rate of 6.0 percent per year, employee hours, at a rate of 4.6 percent. The rise in banking productivity was associated with strongly expanding customer services and with advances in computer technology and their rapid diffusion throughout the industry. However, the spread of branch banking, while enhancing access to banking services, somewhat retarded productivity improvement, partly because scale economies became less favorable.[2]

The labor productivity trend in banking paralleled not only the long-term rate for nonfarm business but also the significant differences in rates of change between the 1967–73 and 1973–80 periods. Over the earlier span, productivity in banking rose at an average annual rate of 2.1 percent, compared with 1.9 percent for all of nonfarm business. Subsequently, the rate decelerated to 0.7 percent a year; for nonfarm business, to 0.9 percent.

Year-to-year swings in the productivity trend were pronounced, ranging from a drop of 6.9 percent in 1974 to a spurt of 6.1 percent in 1976. During the 12-year period, years of decline occurred 4 times, characterized by employment increases in the face of slowed advances (1969 and 1979) or declines in output (1974 and 1980). In such years, restrictive monetary policy (as in 1969 and 1979) or recession (as in 1974 and 1980) constrained the demand for funds. In years when productivity gains ran substantially ahead of the long-term trend average, strong cyclical recoveries or peaks in the demand for banking services occurred (as in 1971, 1973, 1976, and 1977).[3]

Measuring productivity

The labor productivity measure for commercial banking has been developed in accordance with the usual procedures of the Bureau of Labor Statistics for measuring changes in the relation between the output of an industry and the employee hours expended in producing that output. Commercial banking produces a variety of outputs, that is, services to the public. These services have been summed on the basis of weights which reflect —or are close substitutes for—labor requirements per unit of service. The output index was then divided by

---

Horst Brand and John Duke are economists in the Division of Industry Productivity Studies, Bureau of Labor Statistics.

an index of employee hours for commercial banking, so as to obtain an index of output per employee hour, or labor productivity. The labor productivity measure for banking, then, measures the change over time in the ratio of the weighted output of the composite of services to the public to employee hours.

Output has been defined in terms of the three major banking activities: (1) demand deposit transactions, involving the crediting and debiting of checks written by the public, and time and savings deposits transactions, involving deposits upon and withdrawals from accounts held by the public; (2) lending for commercial, consumer, and real estate purposes; and (3) fiduciary, involving the administration of trusts and estates, and the purchase and sale of securities on their account.

The output measure for constructing the indexes of labor productivity in banking has been obtained from data on the quantity of these various services rendered by the banks to the public. As noted, in aggregating these services, the labor requirement per unit of each of the major categories of service in a base period was used as the basis for combining the dissimilar activities. Where labor requirement data were not available, proxies were employed.

The labor inputs used in constructing the productivity measure for commercial banking have been derived from BLS data for employment and employee hours, as reported by banking establishments on the basis of their payroll records. The labor input series, therefore, is an hours paid, rather than an hours worked, measure. No adjustment has been made for differences in skill, experience, or other factors of labor quality, data for such adjustments not being available.[4]

Output of banking services

Output of commercial banks as measured by BLS rose at an average annual rate of 6.0 percent between 1967 and 1980—twice as fast as output of the total private business sector. Sources of the strong growth were the boom conditions of the early seventies and the financial needs they generated; rapid increases in check transactions; relatively greater reliance by business on external funds; and continuously heavy demand for consumer and real estate credit. Also, commercial banks expanded their share of major types of such credit, as well as of time deposits. Moreover, they emphasized the retailing aspects of their services and consequently accelerated branching. Trust department functions also grew apace as pension and other employee benefit funds proliferated.

Banking output rose at a higher rate during the 1967–73 period (7.8 percent a year) than during the 1973–80 span (4.6 percent annually). Output was dampened considerably more in the recession that bottomed in 1975 than in 1970. Loan demand rose more rapidly prior to the 1975 recession than after. The rate of deposit transactions, especially demand deposits, also lost some momentum during the second half of the seventies.

Deposits. Periods of speedup and slowdown aside, demand and time deposits rose rapidly over the long term. The number of demand deposit transactions more than doubled. The velocity of transactions (measured by the number of times a dollar of debits is charged against deposits in a given period) nearly tripled.[5] Furthermore, the importance of demand deposits, a major source of lendable funds, declined in relation to the banks' total liabilities, from 43 percent in 1967 to 27 percent in 1979.[6] Intensifying demand deposit activity, especially during 1967–73, contributed to pressures to introduce such labor-saving procedures and equipment as electronic funds transfers (EFT).[7] Thus, according to a study conducted by the Federal Reserve Bank of Atlanta, the number of checks written by the public rose at an average annual rate of 7.2 percent during the first half of the 1970's and declined to a rate of 5.6 percent during the second half.[8]

In addition to the cash-economizing efforts by the public, evident from the tendency to hold relatively low check balances after the mid-sixties,[9] certain kinds of financial transactions have generated large amounts of account activity. For example, the number of shares traded on the New York Stock Exchange in the seventies averaged nearly 3 times the volume of the sixties. Such trading usually involves multiple funds transfers through the banking system. The number of commodity futures contracts traded on commodity exchanges nearly tripled between the first and the second half of the 1967–79 period.[10] Such trading also entails numerous funds transfers through the banks. The underwriting of stock and bond issues, usually by syndicates, which also rose in the mid- and late seventies, spells the pooling of lender funds and ultimate transfer to the borrower; "(Debits) totaling several times the amount of the financing involved may be recorded in this process. . . ."[11]

There were some developments that tended to retard the growth of transactions and check volume—for example, mergers, which cause book credit and debits to replace bank transactions; bank credit cards, which tend to consolidate individual payments; and the long-term trend towards the output of services relative to goods, making for fewer intermediate transactions. These tendencies were largely offset, however, by the upswings in manufacturing and construction, which result in numerous intermediate transactions.

Time deposits generally expanded rapidly following the progressive liberalization of permissible rates under the Federal Reserve's Regulation Q. Liberalization strengthened the banks' position in retaining and attracting funds which would otherwise have been invested elsewhere. Savings and other time deposits held at the commercial banks by individuals, partnerships, and corporations climbed 106 percent between 1968 and 1980, while demand deposits rose 52 percent. Time deposits accounted for 60 percent of total commercial banking deposits in 1980, as against 54 percent in 1968 (and 35 percent in 1960). Some observers have noted that, in view of such technological advances as electronic funds transfers, the distinction between time and demand deposit accounts has become less significant.[12]

Loans. Expansion of loan output was another source of output growth. The rate of increase of loan output had begun to accelerate prior to 1967, and some of the underlying factors—for example, the emphasis on retail banking—have, of course, a long history. Loan volume being highly susceptible to the impact of the business cycle and of monetary policy on the demand for funds, year-to-year movements proved to be much more erratic for lending than for the volume of deposit transactions. The long-term trend was influenced by the increasing propensity of business to contract for term loans (that is, loans with maturities of more than 1 year); the continued accent upon retail banking; and banks' growing share of mortgage and consumer credit.

Nonfinancial business became more dependent upon funds raised in credit markets than it had been earlier (when corporations had relied more heavily upon internally generated funds). Between 1967 and 1980, the ratio of credit market borrowing by nonfinancial business to its capital expenditures averaged 44 percent, compared with 29 percent for the earlier sixties. The composition of commercial and industrial loans shifted toward term loans, indicating that banks were financing a growing proportion of the plant and equipment outlays as well as of inventories of nonfinancial business.[13]

Banks also stepped up their consumer credit operations. Here, too, growth, of course, originated in earlier years. The share of disposable income devoted to installment borrowing began to rise in the early sixties; at 16 percent in 1967, it continued to rise gradually to 20 percent in 1979. (In 1980, a recession year, the ratio dropped.) Furthermore, the commercial banks expanded their share of holdings of total consumer credit outstanding from 42 percent in 1967 to 49 percent in 1973, remaining at about that level from then on. This gain was linked in part to a shift away from retail store credit, together with growing consumer acceptance of bank credit cards and check credit.[14]

Growth in banks' real estate loans was in large part tied to the expansion in residential and commercial construction of the early seventies and to the strong recovery of both after their slump in the mid-seventies. Banks also captured a larger share of total mortgage holdings, rising from 19 percent in 1967 to 25 percent in 1979 (as the share of insurance companies, in particular, declined). Growth in this area of lending was in recent years also strongly influenced by household borrowing against equity in existing homes.[15]

Table 1. Productivity and related indexes for commercial banking, 1967–80

[1977 = 100]

Year	Output per employee hour	Output	Employee hours	Employees
1967	83.8	52.2	62.3	63.0
1968	85.3	56.3	66.0	66.7
1969	84.0	60.0	71.4	72.0
1970	85.5	64.5	75.4	76.6
1971	88.6	69.1	78.0	79.0
1972	90.3	74.3	82.3	82.9
1973	95.9	83.2	86.8	87.5
1974	89.8	82.9	92.3	92.6
1975	90.0	84.6	94.0	94.2
1976	95.0	91.8	96.6	96.8
1977	100.0	100.0	100.0	100.0
1978	100.7	105.4	104.7	104.9
1979	98.5	108.1	109.7	110.5
1980	92.7	106.1	114.5	115.7
1967–80 average annual rate of change (in percent)	1.3	6.0	4.6	4.5

Trust services. Long-term gains in the trust department output of commercial banks have been associated with the growth in the number of fiduciary accounts and the activity these accounts generate.

Between 1968 (when pertinent data first became available) and 1980, the number of such accounts rose 54 percent.[16] The increase was linked to a more than threefold rise in employee benefit accounts, reflecting the spread of corporate retirement and other employee benefit plans, as well as of pension plans initiated by self-employed persons (Keogh plans).[17] The number of personal trust accounts rose by two-thirds; they still constitute the single most important trust department service, representing more than three-fifths of bank-administered trust accounts. Their rise has in part been related to the desire to shelter current income from taxation, notably as inflation has tended to push incomes into more heavily taxed brackets.[18]

Employment and changing skills

Employment in commercial banking, currently numbering 1.5 million persons, rose 84 percent between 1967 and 1980, or at an average annual rate of 4.5 percent. Average weekly hours tended to decline somewhat, from 37.1 in the first 5 years of the period to 36.5 since then—owing chiefly to the employment of more part-time workers.[19] In no year did aggregate employee hours decline, but their most vigorous rise occurred over the first half of the review period (5.6 percent annually). That high rate was not equaled even during the cyclical recovery following the 1975 slump. From 1974 to 1980, gains averaged 3.8 percent annually.

Nonsupervisory jobs accounted for nearly four-fifths of commercial banking employment in 1980. Of these jobs, office and clerical positions again accounted for four-fifths of employment in the top 100 banks, or 37 percent of total banking employment in 1980. Women staffed 85 percent of these jobs and about one-third of all officer positions. They accounted for two-thirds of banking personnel in 1980, compared with 41 percent of all payroll employment.[20] The prevalence of relatively low-skilled jobs in banking is reflected by the ratio of average hourly earnings in the industry to average hourly earnings in the private economy. Despite the growth of positions in computer programming and systems analysis, that ratio has tended to decline, from 0.87 in the sixties to 0.73 in 1980.

Supervisory jobs in commercial banking have increased in both absolute and relative terms. Such jobs accounted for 23 percent of employment in 1980, as against 17 percent in 1967, an increase of 144 percent. Nonsupervisory jobs rose 65 percent. The ratio of nonsupervisory to supervisory employees thus dropped from 5:1 in 1967 to slightly more than 3:1 in 1980. The increase in supervisory workers was in large part linked with the expansion of branching and the attendant needs for managerial personnel. It was also related to a rise in the number of loan officers, especially for installment loans, and of credit analysts, who are frequently charged with supervisory responsibilities in addition to their regular work.

Skills needed by commercial banking employees have changed considerably, even during the relatively short period examined here. For example, the number of bookkeeping operators has dropped by more than one half since 1969 (and by more than 90 percent since 1960)—owing to the spread of electronic bookkeeping machines and computers, which require substantially fewer operators.[21] Also, tellers have tended to become less specialized as branch banking has spread. The six usual teller classifications—note, commercial-savings, commercial, savings, vault, and all-round—have in many banks been reduced to one all-round teller classification. The practice of classifying tellers by commercial or saving transactions has been declining.[22]

Most bank employees perform tasks related mainly to the banks' depository functions and loan administration. A high school education is generally considered adequate preparation for entry level jobs. Bank officers, on the other hand, usually supervise the various financial and customer services. Loan officers, in particular, are expected to be knowledgeable about the industries from which the individual bank draws its customers and to be sensitive to the often unique problems customers present—problems which frequently require handling on a personal basis. Officers usually have a college degree or an MBA.[23]

The labor inputs of commercial banks thus vary widely in terms of education, training, and skill complexity. Also, wide differences exist between the tasks that can be automated and tasks that cannot be, with the work of loan officers being least susceptible to standardization and automation. However, even in this area, a growing number of supplementary tasks have been computerized.[24]

Fixed investment and technology

Between 1967 and 1979, banks' fixed capital, including structures, furniture, and equipment, rose by a factor of three, while the stock of fixed nonresidential capital in the private business economy as a whole rose by a factor of nearly four.[25] Price indexes to deflate the banks' physical capital stock are not available, so no firm estimate of movements in constant-dollar value can be offered. When the deflators for the total capital stock of business are applied to that of the banks, a rise of about one-third in real terms would result.

About 40 percent of the banks' spending on fixed capital went for equipment and furniture during the review period. In 1980, roughly half of the banks' expenditures for fixed capital other than structures was spent on computers and computer equipment.[26] Fixed capital per employee in commercial banking, at about $16,000 in 1979, ran at three-fifths of the comparable figure for the business economy.[27]

Computer breakthrough. At the root of equipment spending has been the transformation of technology by electronic data processing (EDP). While banks progressively mechanized their routine operations throughout the forties and fifties, the resulting efficiencies improved but gradually. Some students of the field, in fact, attributed these efficiencies more to the specialization of labor and economies of scale in the industry than to mechanization.[28] A 1960 study by the Federal Reserve Bank of Philadelphia stated, "Since World War II, banks apparently have expanded operations more by hiring extra people than by using better equipment."[29] According to the study, the technology used in banks had scarcely changed during most of the first half of the 20th century. The same basic types of cash registers, punched card tabulators, billing and duplicating machines, and check signing equipment found in banks in 1914 were still the mainstay of banking technology at the end of World War II.

Although computer developments during the fifties embodied the principle of machine readability, it was the introduction of magnetic ink character recognition (MICR) in 1958 that made the breakthrough of electronic data processing in banking possible. The computer became an indispensable and major factor in improving banking productivity. Moreover, computer technology has rapidly spread throughout the industry. The first bank automation survey conducted by the American Bankers Association in 1963 showed only 7 percent of all commercial banks to be users of on-premise or off-premise computers. By 1968, 49 percent were users, and in 1980, when the latest available survey was conducted, 97 percent were. The pressures of cost efficiencies, organizational changes, and competition had reduced the proportion of surveyed banks without plans to automate from 84 percent in 1963, to 42 percent in 1968, to virtually nil in 1980.[30] While the larger banks—those with $100 million-plus in deposits—generally maintain their own computer operations, smaller banks have increasingly used their correspondent relations with the larger banks to gain access to computers. As of 1980, 26 percent of all banks operated on-premise computers, while 71 percent used off-premise computers, mostly at correspondent banks.[31] Thus, size of bank, as measured by the dollar value of deposits, does not appear to have seriously inhibited the diffusion of EDP technology in the industry.

The computer has had its greatest impact upon the deposit function, particularly upon check handling. Its full potential, however, is only beginning to be realized, inasmuch as optimally most payments transfers could be processed electronically, that is, without checks. But only a small proportion of payments is so processed at present. Each check is, in effect, "a special piece of currency, created for one transaction only, that has to pass through complex and repeated identification, verification, accounting, and sorting operations before it is retired."[32] Until the mid-seventies, the enormous and steadily growing volume of checks (estimated at 32 billion in 1979) was expected to become too expensive to handle, even by computer. But evolving technology has expanded the check-processing capacity of computers, such that they are thought to be able to "handle any conceivable number" of checks.[33]

The currently most advanced (or "third-generation") computer has a built-in reader-sorter processing capacity of 120,000 checks per hour. Manual reading and sorting of checks, which for many years has involved some machine processing such as high-speed readers, averages 1,200 to 1,400 checks, so that computer use for this phase of the check-handling process represents "order of magnitude" reductions in labor requirements.[34] For other phases of check-handling, comparable productivity advances have not been attained, although so-called rejects or exception items, which in earlier years required laborious interbank correspondence, have come to be processed with great efficiency thanks to cooperative agreements. According to surveys by the Bank Administration Institute, the average labor requirements for all phases of handling checks were reduced by well over one-half between 1970 and 1979 among surveyed banks, mainly because of computerized reading and sorting of checks and more efficient handling of exception items.[35]

In loan operations, EDP has been used for information retrieval, as well as in the administration and bookkeeping operations of such loan categories as installment loans. Credit information, mortgage servicing, bank credit card billing, and accounting have also been among major computer applications. The proportion of personnel in installment loan operations has tended to decline, but the available data do not clearly point to improved productivity in this area of banking. Staff employed in handling bank credit cards—also a type of consumer credit—has expanded in recent years.[36] Business loan operations, which require a comparatively small proportion of bank personnel, have remained relatively labor-intensive—largely owing to their specialized nature and the need for maintaining close customer contact. Even here, however, the computer is playing an increasing role. It is used to provide up-to-date credit analyses and to serve as a bankruptcy predictor. For the larger banks, it makes credit information on a worldwide basis rapidly available. It also facilitates the collection and arraying of data to meet the requirements of regulatory authorities, a task that is otherwise highly labor-intensive.[37]

Computer technology has also contributed to improved productivity in trust departments. It has been primarily applied to information retrieval for purposes of controlling individual accounts.[38] But it has been increasingly used as well in stock trading by trust departments for customer accounts. With trust departments holding the largest share of assets in stocks (49 percent in 1980 by value), such trading accounts for the major part of their activity. The basis of automated stock trading has been a numbering system first devised by the American Bankers Association's Committee for Security Identification Procedures in 1968. The use of committee numbers on stock certificates was mandated by the Securities and Exchange Commission in 1971. This and similar systems have tended to standardize stock identification and have contributed to the transfer of stock without the physical handling of stock certificates. These certificates are "immobilized," that is, they remain in central depositories. Costly errors and redundant bookkeeping entries have been nearly eliminated when trust departments have adopted the technology on which the bankers' stock transfer system is based.[39] Payments and credits involving stock transfers likewise use the system. Relative to output, trust department personnel requirements have been evidently reduced as a result of these and other computer applications.[40]

Electronic Funds Transfer. Potentially the most important use of the computer in banking remains electronic funds transfer (EFT). Although the technology for EFT has existed for nearly two decades, its acceptance by the public has been comparatively slow. Also, a large part of the costs of the check collection system and of demand deposit transactions was absorbed by the Federal Reserve and the banks, rather than passed on to users. Nevertheless, EFT has been increasingly adopted by the banks since the mid-seventies. Competition among financial institutions, as well as the developing cost advantages of EDP over conventional transfer activities, are likely further to speed adoption of EFT technology.[41]

EFT has been increasingly applied in interbank settlements through automated clearinghouses and in basic kinds of teller operations involving customer services, such as deposits and withdrawals, direct deposit of payrolls or other recurring payments, direct bill payment, and transfer of funds from savings accounts to demand deposit accounts and *vice versa*. Point-of-sale terminals, linking merchants with a network of local banks, have also been spreading, although their acceptance and use have remained limited.[42]

Automated clearinghouses have spread rather gradually, although they have not replaced the conventional clearinghouse process as they handle only paperless credit and debit entries between banks. Originating in San Francisco in 1972, automated clearinghouses currently link an estimated 14,000 financial institutions and their offices; they process an estimated 300 million items annually.[43] This number represents but a small fraction of the total number of checks drawn on banks other than the payor's own bank, but it is expected that automated clearinghouses will account for a rising proportion of all items in the clearing process. Among reasons for this expectation have been the success of the direct deposit of social security payments and of a growing number of public and private payrolls; the associated savings in mailing costs; less work incident to replacing lost checks, and the cost pressures linked to the handling of paper items (which despite the increasing efficiency of the process has been more and more complemented or replaced by EFT).[44]

Teller machines. Automated teller machines spread rapidly in the late seventies. Providing customer access by means of a magnetic-stripe bank card and unique identification entered upon a keyboard, the machines receive deposits and payments and dispense cash. Twenty-four hour access is a frequent feature, enhancing customer convenience and reducing waiting lines. Thus, automated teller machines in effect extend banking hours, although banks also view them as "peaking" equipment, helping to reduce lobby traffic during peak hours of business. The machines substitute capital for labor, but for many medium- and smaller size banks, the relatively high fixed costs of the equipment are not offset by savings in labor costs at current volumes of business—a factor that tends somewhat to retard the diffusion of the devices.[45] According to one authority, 19,000 automated teller machines were in use at the end of 1980, each averaging about 4,600 transactions per month, more than 2.5 times the volume 4 years earlier—signifying rapid consumer acceptance of this technology.[46]

The banks have also installed much technologically advanced equipment other than computers and teller machines. For example, word-processing equipment is now being operated in four-fifths of the larger and two-fifths of the smaller banks. Optical character recognition equipment—used, for example, in the processing of credit card charge slips, checks, and direct bill payments—has likewise been installed in most larger banks.[47]

The growth of branch banking

The number of commercial banking firms barely rose 5 percent between 1967 and 1979. But the total of banking offices increased 62 percent, mostly reflecting a doubling in the number of bank branches, and a continuing shift of offices towards the suburban population centers of metropolitan areas. The average population served per bank office declined from nearly 6,000 persons in 1970 to 4,400 in 1980.[48] The decline suggests that banking services became more widely and conveniently available to the public. Current-dollar disposable income per capita nearly tripled during 1967–80 (as did personal consumption expenditures), and households generated an expanding volume of banking business, supporting the spread of branch banking.

Most banks are comparatively small. Those holding total deposits of up to $50 million represent 79 percent of all commercial banks, but in 1979 accounted for only 15 percent of total deposits. Smaller banks usually maintain correspondent relations with the larger banks, and this relation amounts to a "form of multi-office banking."[49] Some of the efficiencies or customer utilities associated with large-scale banking are likely, therefore, to be shared throughout most of the industry.

The larger banks, however, are dominant. The share of deposits held by the Nation's largest banks—those with deposits of $500 million or more—was 62 percent in 1979. These banks constitute little more than 2 percent of total banks. Moreover, in metropolitan areas, the two largest banking organizations usually hold between 55 percent and 67 percent of deposits (the ratio tends to be lower in unit banking States, higher in statewide branching States).[50] Adoption of computer technology has been shown to be closely associated with bank size, as well as with holding company affiliation.[51]

As might be expected, banking employment is also concentrated in the bigger banks. Banks holding $500 million or more in deposits employed 56 percent of all banking personnel in 1979. Banks with less than $100 million in total deposits—89 percent of all banks—employed 27 percent of all personnel.[52]

Among changes in the competitive pattern of financial institutions that have affected banks has been the spread of NOW (negotiable order of withdrawal) accounts at thrift institutions; their effect on the share of time deposit accounts at commercial banks, however, cannot be assayed yet. In some other areas, the role of commercial banks has been eroded. More efficient corporate cash management, spurred by high interest rates and advanced information technology, has diminished the relative importance of demand deposits. Also, commercial banks have evidently been unable to expand their share of credit cards (15 percent of 600 million outstanding cards in recent years). Also, business and consumer credit extended by very large department store chains, automotive companies, farm equipment makers, and EDP manufacturers grew in importance until the early seventies, although their share of financial assets has apparently stabilized since.[53]

Outlook for the industry

The diffusion of EFT is likely to help improve labor productivity in commercial banks in the years ahead. During the late seventies, doubts about its widespread acceptance were expressed in some quarters.[54] Resistance by consumers to abandoning payment by check and their fear of loss of control over balances were cited as two reasons. Regulatory questions concerning the off-premises installation of automated teller machines were another. Also, smaller banks were believed to have opposed EFT because of possible competition from big money-center banks. These obstacles to the diffusion of EFT have so far been only partly overcome. However, cost considerations seem likely to compel its more rapid adoption. To illustrate, in a study of the benefits of electronic government payments done in 1977, the Federal Reserve found the costs of EFT to run nearly two-thirds below the costs of processing checks.[55] The ratio has lessened since then, for the scale economies of EFT have continued to improve, and processing and mailing costs of checks to rise.

Direct deposit of payrolls and of other recurring payments, and direct bill payment will likely also expand, partly owing to the costs of float, which banks must assess as an explicit cost under recent legislation, as well as because banks must offset the cost of handling checks against interest on demand deposits (where such interest is offered). Thus, resistance to EFT is likely to lessen as costs of processing paper items rise—speeding its diffusion.

Continued technological advances and the labor savings expected from them will probably also arise from intensified competition by nonbank financial institutions. Thus, money market funds have come to compete with time and saving deposits for both the small and large investor's dollar, and this, too, may contribute to restricting commercial banks' output growth.[56] Also, more than 80 percent of all household and virtually all business firms had checking accounts in 1977, so that the expansion of banking services from including additional households is quite limited. A partially offsetting factor may be a continued rise in cash withdrawals from automated teller machines, which are believed to be smaller and more frequent than withdrawals by cashing checks.[57] The convenience in the use of banking services made possible by the machines may encourage the banks to adopt product lines similarly appealing to customer convenience.[58]

With the spread of EFT, and other computerized and automated transactions, banks' labor requirements per unit of output are bound to continue to decline. Moreover, new branch staffing needs should be decreasing, partly because of the technological developments discussed, partly because of the already low level of population served per branch, and the consequent abatement in the number of new branches opened. Hence, commercial banks will probably become less important as a source of added employment in the years ahead—also indicated by BLS projections to 1990, which imply a slower rate of banking employment growth than over the past decade. □

FOOTNOTES

[1] Commercial banks are establishments primarily engaged in accepting deposits from the public and making loans and investments. They are designated as No. 602 in the Standard Industrial Classification (SIC) Manual of the Office of Management and Budget. The industry is part of SIC 60—banking, which also includes Federal Reserve Banks, mutual savings banks, trust companies not engaged in deposit banking, and establishments performing functions closely related to banking. Nonbanking subsidiaries of bank holding companies are not included; they are separately classified by primary activity. See *Federal Reserve Bulletin*, December 1972. Commercial banks account for approximately 90 percent of the employment of the total SIC 60 group.

A detailed description of banking output and of the procedures followed in measuring banking productivity, output, and employee-hours, as well as the weighting scheme underlying the output measure, is available upon request.

[2] There is wide agreement among industry observers that scale economies in banking have declined with the spread of branching—that is, more resources, including labor inputs, are required per unit of output. Among definitive studies are *Costs in Commercial Banking*, by Frederick W. Bell and Neil B. Murphy (Federal Reserve Bank of Boston Research Report No. 41, April 1968), and "Economies of Scale and Marginal Costs in Banking Operations," by George J. Benston (*The National Banking Review*, June 1965), reprinted in that report. Industry observers confirm that the tendencies analyzed in these works have persisted.

[3] Professor Charles F. Haywood of the College of Business and Economics, University of Kentucky, interprets the swings in commercial banks' labor productivity as follows: ". . . (At) the beginning of an upswing, banks have some slack in manpower and can increase output somewhat without increasing the rate of new hires. At some point in the upswing, the rate of new hires has to be increased. By the time these new hires are in place, the upswing in the economy is near its end and recession soon follows. There may also be some variation in labor turnover rates related to cyclical variation in the economy that affects input-output relationships in banks . . . (As) turnover rates are high in banking, cyclical variation in such rates could have significant effects on productivity." Communication to the BLS Office of Productivity and Technology.

[4] Among authorities upon whose conception of the banks' functions and output the BLS definition is partially based is Professor Donald Hodgman of the University of Illinois. Hodgman has viewed banking activity as consisting of a bundle of services, grouped into three categories: management of the national payments mechanism; intermediation between borrowers and lenders; and specialized financial services (of which trust activities are by far the most important ones). See Donald Hodgman, *Commercial Bank Loan and Investment Policy* (Urbana, University of Illinois, 1963), p. 165 ff; and John Gorman, *Comment*, "Real Output and Productivity of Banks," in Victor R. Fuchs, ed., *Production and Productivity in the Service Industries* (New York, National Bureau of Economic Research, 1969), p. 189 ff.

[5] See *Banking and Monetary Statistics, 1941–1970*, Board of Governors, Federal Reserve System, p. 321 ff., for a detailed explanation of the turnover rate of demand deposits.

[6] These and other data on commercial banks' shares in financial assets or liabilities were calculated from data from *Flow of Funds Accounts* (Board of Governors, Federal Reserve System), various recent issues.

[7] "Earliest concern with the payment system was rooted in the fear that growing check volumes posed a threat to the continued satisfactory performance of the system. Studies sponsored by the Federal Reserve System and by several national associations of commercial banks in the 1960's placed virtually their entire emphasis on two areas: measuring the national check volume, the pattern of the flows of checks into and through the banking system, and check processing costs; and offering technical and economic feasibility assessments of electronic alternatives of the time to check clearing and collection system. The emphasis throughout was on the use of electronic means to replace checks, or to reduce check handling, through systems created and cooperatively operated by groups of commercial banks, with a key role implied or advocated for the Federal Reserve System." Edwin B. Cox, "Developing an Electronic Funds Transfer System: Incentives and Obstacles," *The Economics of a National Electronic Funds Transfer System*, proceedings of a conference held in October 1974 (Federal Reserve Bank of Boston), p. 16.

[13] Term loans rose from 40 percent of total commercial bank loans in 1967 to 44 percent in 1973 and 48 percent in 1978.

[14] For some reasons why banks attempt to expand their credit card systems, see "EFT in the United States, Policy Recommendations and the Public Interest," The Final Report of the National Commission on Electronic Fund Transfers (Washington, October 1977), p. 134. See also *Bank Credit-Card and Check-Credit Plans* (Board of Governors, Federal Reserve System, July 1968). Banks' adoption and operation of credit plans of their own has had significant implications for their output: although credit cards result in consolidation of payments and, therefore, reduce the number of check transactions, they generate sales drafts which must be cleared through merchant's deposit accounts. Thus, they augment "the paperwork burden to the extent that (they replace) cash in a retail transaction" (p. 63.)

[26] Information on the average annual expenditures per bank for computer equipment, 1980–82, is provided in table 224 of *National Operations/Automation Survey, 1981* (Washington, American Bankers Association).

[27] The prices for computer hardware, as well as for calculating and accounting machinery, widely used by the banks, rose much more slowly than producer durables prices generally or tended to decline over part or all of the review period. See Robert B. Archibald and William S. Reece, "Partial Subindexes of Input Prices: The Case of Computer Services," *Southern Economic Journal*, October 1979, pp. 528–40. The authors show that second generation computers, manufactured for large business uses by IBM, dropped in price by 85 percent between 1970 and 1975. Reasons for the drop are discussed by them. At present, the BLS imputes movements in the value of computer hardware to the office and store machines and equipment group.

Cosmetics industry achieves long-term productivity gains

But recent declines have beset an industry in which productivity has grown rapidly since 1958; gains have been associated with more efficient plants, improved technology, and an expanding line of products which serve changing markets

PATRICIA S. WILDER

As measured by output per employee hour, productivity in the cosmetics and other toiletries industry rose at an average annual rate of 4.0 percent from 1958 to 1980. The rate of growth was substantially higher than the 2.8-percent gain for all manufacturing.[1]

The rise in productivity resulted from a rapid expansion in output, which increased at an average annual rate of 7.3 percent, and a more moderate increase in employee hours, 3.1 percent. Productivity gains have resulted primarily from a trend toward fewer and larger plants producing a greater level of output, and continued improvements in production and packaging operations, such as those of lipstick and toothpaste.

The movements in output per employee hour have not been steady. From 1958, annual increases in productivity ranged from 14.9 percent to 0.4 percent. Declines in productivity occurred in 6 years, the most recent and largest in 1980, when it dropped 11.4 percent. (See table 1.)

Productivity growth can be divided into three distinct subperiods, 1958–65, 1965–70, and 1970–80. The first period was marked by substantial growth in the industry. Larger capacity plants came on line and productivity grew at a rate of 7.5 percent annually. The growth was associated with a rapid rate of increase in output of 10.9 percent. However, employee hours increased at a slower pace—averaging 3.1 percent.

From 1965 to 1970, productivity growth slowed significantly, averaging only 0.2 percent a year. Although output continued to expand at a high rate of 7.0 percent per year, employee hours increased at almost the same rate, 6.8 percent. The industry at this time was undergoing a more pronounced period of expansion. Data available for 1963 and 1972 show a 91-percent increase in employment in establishments with 500 persons or more. The increase in the number of these large establishments (from 15 to 27) with the normal staffing and startup problems no doubt retarded productivity growth temporarily.

After 1970, productivity growth resumed at a rapid pace, averaging 5.7 percent annually through 1977. Beginning in 1978, three successive declines in productivity occurred. The decrease recorded in 1978 was less than 1 percent. However, a decline of 6.2 percent in 1979, followed by a drop of 11.4 percent in 1980, reduced the average annual gain in productivity to 2.7 percent during 1970–80. The decreases in 1979 and in 1980, a recession year, were related to similar large declines in output. However, employee hours did not follow output, but instead increased 2.3 percent in 1979 and 1.3 percent in 1980.

Output increases fourfold

Productivity growth in the cosmetics and other toiletries industry is closely linked to output growth, which has increased fourfold since 1958. Factors affcting this growth have been a larger population, the growing

---

Patricia S. Wilder is an economist in the Division of Industry Productivity Studies, Bureau of Labor Statistics.

number of working women, and extensive advertising and sales promotions.[2]

The industry is highly competitive, and this competition has spurred manufacturers' efforts to expand the range of their products. Many new products and lines have been introduced to meet changing consumer needs and preferences. For example, because of the increased number of women entering the work force, more products have been developed to meet their needs. Also, greater acceptance of the industry's products by men has been a factor in output growth. They are purchasing more fragrances and skin care products such as colognes, after-shave lotions, and moisturizers. Output growth has also been spurred by new products specifically designed for ethnic populations and for older consumers. Growth has also occurred in skin treatment and sun care products because of an increased concern about aging skin and the rise in the incidence of skin cancer and its relationship to ultraviolet sunrays.[3]

Another factor that has contributed to output expansion has been the greater use of synthetic substances in cosmetic and toiletry preparations. Increased use of synthetics, which are often less expensive, to supplement or replace some of the scarce natural products derived from plants and animals and to serve as the bases for new products has enabled the industry to meet demand and to expand its market.

Because demand for cosmetics and toiletries has been high, some analysts had considered the industry to be nearly recession-proof.[4] Indeed, until 1979, only two decreases in output were noted in this study and both were less than 1 percent. However, in 1979, output declined 4.1 percent and in 1980 a further drop of 10.3 percent occurred. These two decreases in output had the effect of reducing the long-term average annual rate of growth in output from 8.0 percent (through 1978) to 7.3 percent.

Plant size and employment

An important factor affecting productivity growth in the industry has been the trend toward larger, more efficient establishments. This is reflected in the steady increase in the number of establishments with 500 employees or more. During 1958–80, the number of these establishments tripled (from 11 to 33), as did employment in these plants. An insight into their efficiency is gained from information on value added per employee. In 1977, the most recent year for which data are available, value added per employee in the large establishments was more than $100,000. This was about 37 percent greater than the level in plants having fewer than 500 employees. The trend toward larger plants with their greater production volume has resulted in significant economies of scale, which in turn has aided the industry's productivity growth.[5] Large establishments now account for about 65 percent of the industry's

Table 1. Productivity and related indexes for the cosmetics and other toiletries industry, 1958–80

[1977=100]

Year	Output per hour			Output	Employee hours		
	All employees	Production workers	Nonproduction workers		All employees	Production workers	Nonproduction workers
1958	40.0	39.0	41.7	22.7	56.8	58.2	54.5
1959	43.9	41.9	47.7	26.5	60.3	63.3	55.5

1978	99.3	98.6	100.6	104.5	105.2	106.0	103.9
1979	93.1	93.8	92.0	100.2	107.6	106.8	108.9
1980	82.5	80.2	86.5	89.9	109.0	112.1	103.9
	Average annual rates of change (in percent)						
1958–80	4.0	4.2	3.8	7.3	3.1	2.9	3.3
1976–80	–3.4	–3.8	–2.6	–1.2	2.2	2.7	1.4

value of shipments, compared with 35 percent in 1958.

Overall employment in the industry expanded by more than 90 percent between 1958 and 1980, rising at an average annual rate of 3.1 percent. Employment, at 29,900 in 1958, had risen to 57,200 by 1980. Total employee hours grew at the same rate as employment.

The largest increase in employment occurred during 1965–70, when the industry was expanding more rapidly. Although employment rose 28 percent from 1958 to 1965, it grew 39 percent during 1965–70. Employment growth from 1970–80 moderated substantially, declining in 5 years. The overall increase in employment during the last period was only 7.9 percent.

Compared with all manufacturing, the number of female employees in the industry is high. They accounted for 57 percent of total employment in 1958, increasing to 60 percent in 1980. By contrast, women made up 26 percent of manufacturing employment in 1958 and 31 percent in 1980.

The proportion of nonproduction workers in the industry is higher than in most other manufacturing industries—37 percent of total employment in 1980, compared with 30 percent for all manufacturing. The higher proportion reflects the larger number of professional, technical, clerical, and sales personnel employed.

Although data on the occupational composition of employees in the industry are not available, some insights can be obtained from the broader aggregation, soaps and cosmetics.[6] In 1978, an estimated 5 percent of all workers employed in the manufacture of soaps and cosmetics were chemical and industrial engineers, chemists, and chemical technicians. Sales and clerical personnel accounted for 26 percent of total employment. The industry also employs many semiskilled workers, such as packers, wrappers, examiners, assemblers, and mixers, who made up 33 percent of the work force in 1978.

Technological advances

The industry produces a vast array of products, including shaving preparations, perfumes, colognes, hair preparations, dentifrices, mouthwashes, lipsticks, deodorants, nail products, creams, and lotions. Standards for the materials used in these products have been upgraded and many are now equal to the material specifications for the pharmaceutical industry.[7]

Although the basic processes involved in the production of cosmetics and toiletries have changed little over the period, there have been improvements in the equipment and methods used. Many of these changes have occurred on an in-house basis, with individual plants developing some of their own equipment and modifying or integrating production lines to improve efficiency. An improvement that is widespread throughout the industry is the increased speed of filling and packaging lines.

One of the major processes involved in the production of cosmetics and toiletries is batch preparation of the products prior to packaging. Some improvements have occurred that have increased efficiency in preparing the batches. As volume warrants, the more frequently used raw materials are stored in large tanks and then transferred directly to the mixing tanks via a pipeline system. Previously, the raw materials were received in drums and were manually dumped into the mixing tanks. Semiautomatic controls allow the operator to easily select the necessary raw materials. The final product is moved via pipes to stainless steel storage tanks, where air-controlled pumping systems transfer the batches to the filling lines.

Manufacturers have developed and adopted high-speed filling and packaging equipment for use with large-volume production runs. Small-volume runs or products requiring complex or delicate operations are generally less automated. Much of the equipment used in high-speed production can automatically perform such operations as bottle feeding, product coding, and packing of bottles and boxes into cartons for shipment. One recent innovation in this area is the automatic unscrambler and bottle feeder. Bottles, jars, or caps are automatically sorted and fed directly to the filling lines.

Products in the form of sticks. For lipsticks and other items such as eye shadow, deodorant, and perfume, the basic processing method first involves melting and mixing the base products. Next, the forms, castings, or molds are filled and cooled. Most products are then removed from the forms and are placed into holders. In a few cases, particularly deodorant sticks, filling directly into the holders for molding is possible.[8]

One of the more complicated operations is the production of lipsticks. Preparation of bulk material for lipstick production is done using batch processing. The most complex step is molding the sticks. Their production was formerly performed as a manual operation; however, many manufacturers have adopted automatic or semiautomatic equipment. The equipment consists of a storage container with an attached dosing device and a circular molding table with interchangeable molds that can handle different shapes and sizes of lipsticks. The equipment also includes a feeding table for lipstick bases, and pressurized-air equipment for pushing solidified sticks into the bases. Lipstick covers and bottom labels are automatically put onto the bases. Automatic equipment places the completed sticks into cartons.[9]

Toothpaste production. In the manufacture of toothpaste, automated equipment is now being used that makes the batch process almost one continuous operation—reducing labor requirements. The filling process is done using high-speed equipment and an automated tube feeder. With the high-speed equipment, a dental cream line can now be operated with two persons; previously four or five were needed.

There has also been a change in the material used for toothpaste tubes. The trend has been to switch from metal to laminated plastic tubes, which are generally easier to handle and can be processed about 10 percent faster. Heat sealing the laminated tubes is quicker than crimping metal, thus increasing production speed.[10]

Tubes leaving the filling line are packaged using automatic case packers and palletizers. It now requires two or three fewer people to strap cases, and this equipment has increased the number of pallets that can be packed. The entire pallet load is now automatically wrapped with shrink film (a form of clear plastic wrap).

Fragrances. The production process for perfumes and colognes has changed little because of the unique storage requirements for aging. The batch process is not a continuous operation because, prior to filling and completion, these products must be pumped into storage tanks and left for 3 to 7 days to age. However, some improvements have occurred in the equipment used in filtration and in filling. After aging, perfumes and colognes are chilled to a temperature near freezing. To obtain a crystal-clear product, they are processed through a filter press to remove sediments. The liquids are then pumped to the filling lines through pipelines. Advanced equipment is being more widely used to assure proper filtration and filling. The filling and packaging equipment that is used for other cosmetic products is also used for perfumes and colognes. Considerable labor reductions have occurred because of the availability of more sophisticated high-speed equipment.[11]

Aerosol products. A technological innovation which became widespread in the industry in the 1960's was the aerosol dispenser. Substantial improvements to the aerosol unit, which have reduced labor requirements, have occurred during the last several years. Valves and stems are automatically placed into the aerosol units on the filling line. Previously, this operation was done manually. The valves are then mechanically crimped to allow pressurization. After filling, the aerosol units pass through an explosion-proof area for pressurization and safety checking. The units are also inspected for leakage and are automatically scanned for liquid content.

Scientific instrumentation. For new product development and quality control, the industry now utilizes sophisticated instrumentation such as gas and high-pressure liquid chromatography, mass spectroscopy, and nuclear magnetic resonance.[12] This equipment has reduced labor requirements and increased the speed of the chemical analytical process.

Computer technology has aided productivity growth in several ways. Computers are increasingly being used for jobs such as flow and measurement of raw materials, formula calculations, mixing operations, and are already widely used in the batch operations for verification of the individual batches. Also, computers have assisted in reducing the turnaround time for products and in decreasing the amount of paperwork.[13] They are being used more often in warehouses to perform such tasks as product location, inventory control, and shipping documentation. In the important area of sales, marketing analysis is more easily accomplished with computer-based information systems.

PRODUCTIVITY GROWTH should continue because of improvements in the production processes and in the equipment used. Increased utilization of computer technology may also contribute to productivity gains.

Demand for the industry's products is expected to rise. According to industry analysts, some of the fastest growing categories are facial treatments, hair straighteners, manicuring products, after-shampoo products, sun care products, and men's fragrances. Factors which are believed to be important for future industry growth include increased use of cosmetics and fragrances by men, growth in products promoted for the ethnic populations, more products to meet the needs of older consumers, and the growing awareness of skin care. ☐

——FOOTNOTES——

[1] The cosmetics and other toiletries industry comprises establishments primarily engaged in manufacturing perfumes (natural and synthetic), cosmetics, and other toilet preparations. This industry also includes establishments primarily engaged in blending and compounding perfume bases; and those manufacturing shampoos and shaving products, whether from soap or synthetic detergents. The industry is designated as SIC 2844 in the Office of Management and Budget's *Standard Industrial Classification Manual, 1972.* Data prior to 1958 are not comparable. All average annual rates of change are based on the linear least squares trends of the logarithms of the index numbers. Extensions of the indexes will appear in the annual BLS Bulletin, *Productivity Measures for Selected Industries.*

APPENDIX: Measurement techniques and limitations

Indexes of output per employee hour measure changes in the relation between the output of an industry and employee hours expended on that output. An index of output per employee hour is derived by dividing an index of output by an index of industry employee hours.

The preferred output index for manufacturing industries would be obtained from data on quantities of the various goods produced by the industry, each weighted (multiplied) by the employee hours required to produce one unit of each good in some specified base period. Thus, those goods which require more labor time to produce are given more importance in the index.

In the absence of physical quantity data, the output index for the cosmetics and other toiletries industry was constructed using a deflated value technique. The value of shipments of the various product classes were adjusted for price changes by appropriate Producer Price Indexes to derive real output measures. These, in turn, were combined with employee hour weights to derive the overall output measure. These procedures result in a final output index that is conceptually close to the preferred output measure.

The indexes of output per employee hour relate total output to one input—labor time. The indexes do not measure the specific contribution of labor, capital, or any other single factor. Rather, they reflect the joint effect of factors such as changes in technology, capital investment, capacity utilization, plant design and layout, skill and effort of the work force, managerial ability, and labor-management relations.

The office furniture industry: patterns in productivity

Product proliferation and short production runs limited the use of laborsaving equipment in office furniture establishments; as a result, productivity grew only moderately during 1958–80

J. EDWIN HENNEBERGER

Productivity growth (as measured by output per employee hour) in the office furniture industry[1] has been low, in large part because of relatively short production runs engendered by product proliferation. Between 1958 and 1980, the industry posted an average annual productivity gain of 1.8 percent, substantially below the 2.8-percent rate for all manufacturing industries. The gain resulted from growth in output of 5.5 percent, annually, and employee hours of 3.6 percent.

In many industries, declines or small gains in output are associated with reduced or even negative growth in productivity. This seems to be true of the office furniture industry as a whole. (See table 1.) Thus, in the 9 years in which output either declined or grew at a less than average rate, productivity either fell or grew at a less than average rate in 5 of these years.

The trend in productivity for the overall office furniture industry must be viewed in light of the underlying trend movements of the two component industries—wood office furniture and metal office furniture. Metal furniture is the dominant industry in the office furniture group, employing about two-thirds of the 53,000 workers and accounting for roughly the same percent of shipments. Although both industries exhibited nearly the same growth in productivity between 1958 and 1980 (1.7 percent for wood furniture and 1.8 percent for metal furniture), the growth in output and employee hours was more diverse, with both output and hours growing at much higher rates in the wood component (7.2 percent and 5.5 percent) than in metal (4.6 percent and 2.8 percent).

The metal office furniture industry, which experienced five output downturns between 1958 and 1980, was, nevertheless, able to maintain productivity growth in all but 2 of these years. This suggests that the industry's work force is flexible and can be rapidly reduced if industry sales are declining. However, the wood office furniture industry was never able to maintain positive productivity during the six declines in output from 1958 to 1980. The more highly skilled work force, utilizing craftworkers, in the wood segment may be more difficult to periodically layoff and rehire.

Productivity trends have varied

The industry's long-term productivity growth can be divided into three periods (table 1). From 1958 to 1966, productivity grew at a rate of 3.6 percent annually. Slowing dramatically, productivity growth advanced by only 0.1 percent per year during the middle time span—1966 to 1975. However, from 1975 to 1980, the rate of advance increased to 5.1 percent per year.

Recession-induced falloffs were particularly acute from 1966 to 1975. During the 1970 recession, industry output dropped 17 percent while employee hours were reduced by 6.6 percent. Consequently, productivity in 1970 fell by more than 11 percent. During the 1974–75 recession, output declined 5.3 percent in 1974 and 17.7 percent in 1975 while productivity posted its largest falloff in 1974 (−8.3 percent). More recently, productivity exhibited positive growth during the short reces-

Table 1. Productivity and related indexes for the office furniture industry, 1958–80

[1977 = 100]

Year	Output per employee hour	Output	All employee hours	Employees
1958	64.0	33.1	51.7	51.8
1959	69.8	37.5	53.7	52.9
1960	70.4	39.4	56.0	54.7
1961	72.5	38.4	53.0	51.8
1962	74.4	42.1	56.6	55.8
1963	75.9	45.6	60.1	58.7
1964	82.1	50.8	61.9	60.0
1965	84.2	57.5	68.3	64.9
1966	86.7	67.9	78.3	74.7
1967	86.5	69.7	80.6	78.2
1968	85.2	70.9	83.2	78.7
1969	88.0	81.4	92.5	88.9
1970	78.2	67.6	86.4	82.7
1971	83.9	64.8	77.2	74.9
1972	91.8	82.7	90.1	87.3
1973	90.6	87.5	96.6	94.4
1974	83.1	82.9	99.8	96.9
1975	85.5	68.2	79.8	81.8
1976	89.7	75.8	84.5	85.6
1977	100.0	100.0	100.0	100.0
1978	100.1	108.1	108.0	107.8
1979	107.3	121.1	112.9	110.9
1980	108.9	125.9	115.6	118.4
	Average annual rates of change			
1958–80	1.8	5.5	3.6	3.8
1958–66	3.6	8.4	4.6	4.1
1966–75	0.1	1.4	1.4	2.0
1975–80	5.1	13.9	8.3	8.0

sion in 1980. However, this gain in productivity (1.5 percent) was somewhat less than the industry's long-term growth (1.8 percent per year).

Among the component industries, the same midterm pattern of productivity slowdown is evident. (See table 2.) From 1958 to 1966, productivity advanced in both industries at about 3.6 percent per year. But from 1966 to 1975, productivity fell at an annual rate of 1.1 percent in the wood component while advancing by only 0.5 percent per year in the metal furniture industry. Rebounding from the recession-marked middle period, productivity advanced sharply from 1975 to 1980 in the wood and metal industries—7.2 and 3.8 percent, respectively. Output in this recovery period was up sharply in both industries, paced by the nearly 22-percent average annual growth in wood furniture. Lagging somewhat behind wood furniture, the output of metal furniture increased by about 10 percent per year during this later period, as market share was lost to the more natural look and feel of wood.

Office furniture demand growing

Between 1958 and 1980, output of the office furniture industry grew at an average annual rate of 5.5 percent per year, substantially above the 3.8-percent average rate for all manufacturing industries. A number of factors have shaped the demand for office furniture and the industry's output growth. Some of these factors have included the amount of available office space, growth of the white-collar work force, replacement demand, and the introduction of new products.

The most important factor influencing the long-term growth of office furniture undoubtedly has been the growth of the white-collar or office work force. Between 1958 and 1980, white-collar workers have grown from about 27 to nearly 53 million. Currently, officeworkers account for slightly more than one-half of the total employed work force.[2] This translates into a 2.9-percent average annual increase. Available office space also is a determinant of office furniture demand. The amount of public and private detached office space doubled between 1958 and 1980.[3]

As the stock of existing office furniture grows, the demand for replacement of wornout or obsolete equipment grows also. The data suggest that in recent years roughly one-third of office furniture production has been consumed by the replacement market.[4]

The introduction of new products also stimulates increased demand for office furniture. In the past, office furniture usually consisted of desks, chairs, tables, and storage equipment, sold as individual pieces. Now, modular or systems furniture is sold as complete integrated packages that include movable partitions, storage components, and service modules. Advantages claimed

Table 2. Productivity indexes for the office furniture and two component, 1958–80

[1977=100]

Year	All office furniture	Wood furniture	Metal furniture
1958	64.0	67.1	64.5
1959	69.8	69.5	71.6
1960	70.4	68.0	72.7
1961	72.5	70.5	74.7
1962	74.4	69.9	77.9
1963	75.9	80.4	75.9
1964	82.1	84.5	82.9
1965	84.2	82.8	86.3
1966	86.7	85.9	88.3
1967	86.5	88.1	87.6
1968	85.2	87.7	86.2
1969	88.0	91.9	88.5
1970	78.2	83.9	78.0
1971	83.9	81.2	86.4
1972	91.8	84.5	96.7
1973	90.6	78.5	97.9
1974	83.1	83.0	84.5
1975	85.5	80.5	88.9
1976	89.7	81.9	94.8
1977	100.0	100.0	100.0
1978	100.1	100.7	98.9
1979	107.3	110.7	104.8
1980	108.9	109.2	108.6
	Average annual rates of change		
1958–80	1.8	1.7	1.8
1958–66	3.6	3.5	3.6
1966–75	0.1	−1.1	0.5
1975–80	5.1	7.2	3.8

for systems furniture include design flexibility, more efficient use of floor space, low rearrangement costs, and built-in electrical outlets. In recent years, systems furniture has outpaced the growth of conventional office furniture. Currently, systems furniture accounts for about 20 percent of the total office furniture market. Computers and word processors, which require support furnishings, have also resulted in increased demand for office furniture.

Industry employment more than doubles

The number of employees in the office furniture industry increased from 23,000 in 1958 to about 53,000 in 1980. Sustained expansion of the work force during the 1960's accounted for much of this growth.

While the overall employment growth for the industry was 3.8 percent per year from 1958 to 1980, employment trends varied among the subindustries. The work force in the wood office furniture industry expanded at an average of 6.0 percent per year. The metal furniture industry grew at less than half of that—2.8 percent per year.

Compared with other manufacturing industries, office furniture production is relatively labor intensive. About 10 percent more production worker hours are needed to generate $1 of added value in office furniture than in all manufacturing. Among the component industries, wood office furniture is the most labor intensive.

Production workers accounted for 79 percent of total industry employment in 1980, down slightly from the 81 percent reported in 1958. About 25 percent of the industry's workers in 1980 were women, slightly less than the 31 percent level for all manufacturing. Average hourly earnings of production workers—$5.92 in 1980—were somewhat below that of the all manufacturing rate of $7.27. Over the long term, employee turnover has been slightly below that of the all manufacturing rate.

Industry establishment size increasing

Although office furniture production is geographically dispersed throughout the United States, there is a large concentration of firms in Ohio, Indiana, Illinois, Michigan, and Wisconsin, with many plants clustered in and around Grand Rapids, Mich. Until World War II, the Grand Rapids area had been a major center for household furniture. After the war, the household furniture industry dispersed, and commercial and office furniture manufacturers moved in to fill the void.

From 1958 to 1977, the number of establishments in the industry has been growing. In the wood segment, the number of establishments more than doubled, while in metal furniture, the number increased by only 25 percent. For the industry as a whole, average employment size per establishment increased by about 12 percent. During the same period, companies primarily manufacturing office furniture increased from 289 in 1958 to 486 in 1977—most of this growth occurring in the wood furniture segment. At the same time, the proportion of industry shipments accounted for by the four largest companies in each industry increased modestly.

Between 1975 and 1980, the average annual growth in capital expenditures per employee was lower for the office furniture industry than for all manufacturing. For example, from 1958 to 1975, capital expenditures per employee grew at an annual rate of 6.3 percent in office furniture, while the all manufacturing rate over the same time period was 7.5 percent. Productivity growth over this period was also lower in the office furniture industry than in all manufacturing. From 1975 to 1980, however, capital expenditures per employee accelerated to 29.6 percent per year, compared with a rate of 11.1 percent for all manufacturing. Productivity from 1975 to 1980 increased sharply also, growing at a rate of 5.1 percent. The level of expenditures per employee, however, has been substantially less than all manufacturing. In 1980, the office furniture industry expended roughly $2,900 per employee for new capital equipment while the all manufacturing average was almost $3,700.

Manufacturing innovations limited

Typically, production in the office furniture industry takes place at mechanized work stations with workpiece transfer accomplished by conveyor line, forklift truck, or handcart. The wood furniture industry employs general purpose woodworking machinery such as saws, planers, glue presses, and sanders. Basic operations in the metal furniture industry include metal cutting, stamping, welding, and tubeforming. With minor differences, both industries have common operations such as painting and upholstering. Obviously, many of the processes used for manufacturing wood furniture bear little resemblance to those used for metal furniture. However, even within the component industries, variations in equipment and processes are evident. This is particularly true of wood furniture. Some of the finer grades are produced almost entirely by hand, while the less expensive grades are produced in assembly line fashion.

Product proliferation is a problem within the office furniture industry, and this has hindered the introduction of special purpose and highly efficient machinery and equipment. While the household furniture industry finds it relatively easy to drop product lines and styles, office furniture companies must maintain the capacity to produce old as well as new product lines. This problem is particularly acute in the more expensive wood office furniture lines. Reorders of wood furniture must match style as well as wood grain pattern and color (which may not be the same as when the pieces were new).

Therefore, the potential number of product types, styles, and colors, coupled with the bulkiness of furniture, discourage factories from accumulating large inventories of finished goods. Most office furniture, perhaps as much as 90 percent, is for order rather than inventory. Office furniture dealers do not stock large inventories either; rather, an accumulation of customer orders is periodically sent to the factory. This results in short production runs of individual items.

This diminished ability to control production runs may be one of the reasons productivity growth in the office furniture industry has been less than that of the household furniture industry.[5] The office furniture industry must remain even more flexible in terms of production capabilities than household furniture manufacturers, many of whom are also troubled by short, inefficient production runs and difficulty in incorporating highly specialized and efficient equipment. Nevertheless, some notable advances in the technology of manufacturing office furniture have been introduced.

In the wood office furniture industry, one of the most pronounced trends in innovation has been increased use of particleboard. While the primary impetus for the expanded usage of particleboard has been its lower cost in relation to the cost of solid lumber, the industry has focused considerable attention on new technologies to handle the material. A wide variety of surface laminates and films and application techniques have eliminated several time-consuming production and assembly operations. Groove-folding, a technique whereby V-shaped grooves are cut in the particleboard substrate, but not through the flexible surface material, produces seamless furniture edges which are held in place by the continuous outer wrap.[6]

Although somewhat hampered by increased petrochemical prices in recent years, the use of plastic materials has simplified construction and added strength to furniture components, and can also produce mar-resistant surfaces. Reconstituted wood veneer, another advance in materials, has uniform thickness, grain, and quality and can be evenly stained. Its use eliminates the need for the labor intensive procedure of manually grading, selecting, and removing defects from natural veneers.

In addition to new materials, notable advances have occurred in woodworking machinery. Abrasive planing, introduced in the early 1960's, combines heavy stock removal with direct dimensioning at the sanding machine.[7] Machines which glue and trim veneer strips to the edges of particleboard can eliminate the complicated set of clamps and pressure bands which formerly had to be locked in place until the glue dried.

In the metal office furniture industry, machines have recently been installed that automatically position and cut shapes into the large flat metal blanks that later will be fashioned into desks, file cabinets, and so forth. This equipment is more efficient because it does not require moving the workpiece to a separate machine for each cut. Also, setup time is considerably reduced.

Savings in the time needed to produce tubular shapes have been accomplished by new tubeforming and cutting equipment. Tubemaking, which starts from flat coiled steel, has been speeded up by the use of automatic welders which join the ends of the coils so that the tubeforming equipment need not be shut down while coils are being changed.

Metallic inert gas (MIG) welding has largely supplanted most other forms of welding. Its advantage is that the parts being joined do not have to be as thoroughly cleaned as with brazing. Although robot welders are not common, automatic welding is. Once travel and angle of the welding arm have been adjusted, a worker is required only to load and unload workpieces onto and from the equipment.

Although not designed specifically for the metal office furniture industry, automated parts inventory storage and retrieval systems are being used by several plants in the industry. Operating under the control of a computer which "explodes" or breaks down orders for the required number of finished pieces of furniture into the necessary parts demand, robot crawlers and unmanned forklift trucks retrieve and deliver the parts to various pickup stations where they are transferred to the assembly line in the correct sequence for manufacture.

Upholstering, an operation which is similar in both wood and metal office furniture, is a particularly labor intensive operation and requires a skilled work force. Although still used in many plants, manual pattern layout and fabric cutting have in some cases been phased out, superseded by diecutting of fabric. Computer-controlled cutting equipment, which combines high speed with accuracy and eliminates manual pattern layout, is also available.[8] Steam tables, installed at upholsterers' work stations, expand the cut fabric workpiece. Once removed from the steam and stapled around the foam rubber cushion, the fabric shrinks back to its normal size and becomes taut. Airpowered plunger tables, used to compress the fabric-covered foam shape, have made button insertion and tiedown operations easier.

Electrostatic finishing, used widely by the metal furniture industry, can be used successfully on wooden furniture,[9] resulting in increased labor productivity in the finishing area and a substantial reduction in material and maintenance costs. Automatic electrostatic spray lines allow closer spacing of pieces to be painted and, thus, greater efficiency. With these automatic lines, color changeover is automatic and can be done in 30 seconds rather than the 2 minutes previously required on the nonautomatic electrostatic lines. Electrodeposition lines, which are powdered coatings in a medium of either air or water, are particularly efficient with respect to labor, materials, and solvent emissions.

Likewise, both the metal and wood office furniture industries have shared the advances made in portable, handheld power fastening tools, resulting in added worker efficiency through more power, greater capacity, and less weight and maintenance. Productivity has also been enhanced by improved workflow layout, computerized recordkeeping, and new materials such as quick-setting glues and improved finishes.

Recent trends may continue

If continued, the industry's capital spending surge of the last few years may provide the plant and equipment necessary to maintain the recent above average growth in productivity. However, the current economic downturn may have a negative effect on demand and productivity.

Although the full consequences of the current economic downturn cannot be foreseen, it is worth noting that previous recessions have had only limited effects on the growth of the white-collar work force, one of the key factors in the output growth of the office furniture industry. In fact, even though there have been four recessions since 1958, the total white-collar work force has never declined. With the forecasted continued expansion in the white-collar work force,[10] demand for the industry's products should continue to increase and may, therefore, present the industry with opportunities to expand productivity. Also, the industry's output should be further bolstered if the growth of systems furniture continues.

While the "paperless office" is not as yet a reality,[11] over the long term, the increasing sophistication of electronic office equipment may result in officeworkers becoming more productive. This, in turn, can influence output of the office furniture industry by dampening growth in the white-collar work force and affecting demand and productivity in the office furniture industry. ☐

FOOTNOTES

[1] The office furniture industry is classified as SIC 252 in the 1972 *Standard Industrial Classification Manual* and its 1977 supplement, issued by the U.S. Office of Management and Budget. The subindustries within the office furniture group include establishments that are primarily engaged in manufacturing furniture commonly used in offices—wood (SIC 2521) and metal (SIC 2522).

APPENDIX: Measurement techniques and limitations

Indexes of output per employee hour measure changes in the relation between the output of an industry and employee hours expended on that output. An index of output per employee hour is derived by dividing an index of output by an index of industry employee hours.

The preferred output index for manufacturing industries would be obtained from data on quantities of the various goods produced by the industry, each weighted (multiplied) by the employee hours required to produce one unit of each good in some specified base period. Thus, those goods which require more labor for production are given more importance in the index.

Because data on physical quantities are not reported for the entire office furniture industry, real output was estimated by a deflated value technique. Changes in price levels were removed from current-dollar values of production by means of appropriate price indexes at various levels of subaggregation for the variety of products in the group. To combine segments of the output index into a total output measure, employee hour weights relating to the individual segments were used, resulting in a final output index that is conceptually close to the preferred output measure.

The indexes of output per employee hour relate total output to one input—labor. The indexes do not measure the specific contribution of labor, capital, or any other single factor. Rather, they reflect the joint effects of factors such as changes in technology, capital investment, capacity utilization, plant design and layout, skill and efforts of the work force, managerial ability, and labor-management relations.

The average annual rates of change presented in the text are based on the linear least squares trend of the logarithms of the index numbers. Extensions of the indexes appear annually in the BLS bulletin, *Productivity in Selected Industries.* A technical note describing the methods used to develop the indexes is available from the Division of Industry Productivity Studies.

Productivity in the pump and compressor industry

During 1958–80, the industry experienced long-term advances, reflecting improvements in metalworking machinery and computer aid; but since 1965, productivity has decelerated, being especially slow from 1973 forward

HORST BRAND AND CLYDE HUFFSTUTLER

Output per employee hour in pump and compressor manufacturing rose at an average annual rate of 2.1 percent between 1958 and 1980—compared with a rate of 2.6 percent for manufacturing as a whole.[1] Output increased 4.7 percent a year, employee hours 2.6 percent. Among the sources of the industry's long-term productivity advance were improvements in metalworking machinery, which lies at the core of the production processes for pumps and compressors, and computer technologies, which were increasingly applied to engineering design.

The labor productivity trend for the industry was marked by strong advances during the early part of the period (from 1958 to 1965), followed by deceleration during 1965–73, and a further slowing thereafter. As the tabulation shows, using average annual rates of change in percent, the trend pattern paralleled manufacturing:

	Pumps and compressors	*Manufacturing*
1958–80	2.1	2.6
1958–65	3.4	2.7
1965–73	2.1	2.4
1973–80	1.0	1.8

By 1980, the level of labor productivity in the industry had risen 55 percent from 1958, as against 78 percent for all manufacturing.

The long-term productivity trend, in addition to evidencing divergent medium-term movements, was punctuated by sharp year-to-year swings. These swings were generally related to the business cycle, although they show no uniform pattern. Thus, labor productivity fell steeply in 1960 (3.2 percent), 1975 (5.6 percent), and 1980 (2.6 percent). In these years, output either grew more slowly than employee hours (1960), or fell more rapidly (1975), or fell while hours rose (1980). Yet, in 1961, 1967, and 1971, years when the economy slowed, significant increases in productivity occurred (3.9 percent, 1.7 percent, and 1.5 percent)—which, however, stemmed from drops in employee hours exceeding drops in output.

Years of recovery or boom in which productivity soared to more than twice its long-term rate, displayed a more uniform pattern of change in output and employee hours. In 1959 and 1976, gains in productivity were linked with large output increases but slight employee hour declines.

Separate data for pumps and pumping equipment, and for air and gas compressors, are available only from 1972 forward. Average annual rates of change in labor productivity for the two separate industries compare as follows for the 1972–80 span:

Horst Brand and Clyde Huffstutler are economists in the Division of Industry Productivity Studies, Bureau of Labor Statistics.

	Percent
Pumps and compressors	1.2
Pumps and pumping equipment	1.2
Air and gas compressors	1.1
All manufacturing	1.9

Reflecting contrasting trends in output and employee hours, labor productivity movements in the pump and pumping equipment segment were considerably less volatile than in compressor manufacturing. The former attained a productivity level in 1979 that exceeded 1973 by 7 percent (both years registered cyclical peaks); the latter failed to reattain its 1973 high.

Output increases

Pumps and compressors are used throughout manufacturing and many nonmanufacturing industries, as well as agriculture. Pumps are the second most common machine in use after the electric motor.[2] Compressors generate compressed air, which may be regarded as a form of energy ranking in breadth of use only below electricity, gas, and water, in addition to being indispensable in the transportation of gas.[3]

Between 1958 and 1980, output of pumps and compressors rose 175 percent, or at an average annual rate of 4.7 percent. Manufacturing output grew at a rate of 3.8 percent over the period. Like the long-term trend in the industry's labor productivity, the long-term trend in output rose less after 1965 than earlier, as the following tabulation indicates by showing average annual rates of change in percent:

	Pumps and compressors	Manufacturing
1958–80	4.7	3.8
1958–65	6.5	5.9
1965–73	2.5	3.0
1973–80	4.2	2.5

Output of pumps and compressors reached a peak index level of 115 (1977=100) in 1979, from which it receded slightly in 1980. The dip was caused by a decline in compressor manufacturing, which had climbed 51 percent between 1973 and 1979. Pump and pumping equipment output had risen 22 percent between those 2 years of cyclical highs.

Of the total output of pumps and compressors, the former accounted for about two-thirds, according to the *1977 Census of Manufactures*, the latter for the remaining one-third. Industrial pumps represented more than half of the output of pumps and pumping equipment (other than accessories). Hydraulic fluid power pumps, oil well and oilfield pumps, and other pumps and equipment installed in appliances, fire engines, and structures, made up the remaining output. Parts and attachments constituted close to one-quarter of pump manufacturing output in 1977. Given the often difficult climatic and environmental conditions in which pumps must operate, and the abrasiveness of fluids often transferred by them, speedy replacement of worn and damaged parts constitutes a vital function of the manufacturer, and is the reason for the high proportion of shipments of parts and attachments.

Air compressors accounted for well over one-quarter of the shipments of compressor manufacturers, according to the 1977 census, gas compressors for just under one-tenth. They consisted preponderantly of the stationary type. Portable compressors, which are relatively small machines, made up one-fifth of total air and gas compressor shipments. Industrial spraying equipment also added one-fifth to compressor manufacturers' shipments. Compressors, like pumps, are frequently exposed to rough operating and environmental conditions, hence a comparatively high proportion of shipments (20 percent) represented parts and attachments in 1977.

Factors underlying output growth

In general, growth in the output of pumps and compressors was related to expansion in industrial and public utility demand, particularly during the boom years of the early and mid-1960's; gains in residential and associated public works construction, such as sewage and waterworks, during the 1960's and 1970's; and intensified needs of energy-related extractive and pipeline industries, especially during the 1970's. Foreign trade, too, played an important role in sustaining output: about one-fifth of pump and compressor production was exported between 1972 and 1978.

Expansion in the productive activities of a wide array of users lay at the base of output growth of pumps and compressors. No precise statistical link can be established between the former and the latter. However, movements in the plant and equipment expenditures, adjusted for price changes, by major pump and compressor users are indicative, as are put-in-place data for construction.

Among large-scale users of pumps and compressors was the chemical industry, which accounts for about one-tenth of total pump and compressor output.[4] Chemicals nearly doubled plant and equipment outlays (adjusted for price changes) in the early 1960's, then reduced them. After 1973, however, outlays were once again raised, so that in 1979 they stood nearly twice above the 1973 level. The industry has increasingly used pumps made of fiberglas, plastics, and stainless steel to transfer salt solutions, acid, and chlorine.[5]

Steel mills and blast furnaces, whose capital spending patterns compared roughly with that of the chemical industry over the review period, purchase about 7 percent of pump and compressor output. They use a variety of industrial and hydraulic pumps as well as compressors to move sources of energy such as liquid fuels, as well as water to absorb waste energy. Installation of multistage pumps to achieve higher pressure has, in part, been prompted by the shift from open-hearth to basic-oxygen and electric-arc steelmaking processes. The partial replacement of slabbing mills by continuous casting has required more water, hence a larger number of and more powerful centrifugal pumps.[6]

More than 18 percent of pumps and compressors are bought by energy-related extracting, processing, and distributing industries. Thus, growth in extractive activities spurred the demand for industrial as well as oil well and oilfield pumps. Between 1960 and 1970, the number of crude oil and gas wells drilled dropped sharply (by nearly two-fifths), as did footage drilled (by 27 percent). After 1970, the decline was reversed; in 1978, the two indicators ran 72 percent and 68 percent above 1971 levels. Concomitantly, output of oil well and oilfield pumps, which had risen at an average annual rate of less than 4 percent between 1958 and 1973, soared to a rate of more than 10 percent between 1973 and 1980. Oil extraction also requires reciprocal pumps for mud circulation; submersible centrifugal units to lift the crude oil; and centrifugal pumps for waterflooding (to prevent subsidence and maintain pressure).[7]

Compressors are required in oil drilling and oilfield maintenance operations, and particularly in secondary recovery efforts. The continued expansion of natural gas pipelines (whose mileage increased 9 percent between 1973 and 1978) spelled the installation of additional large compressors for gas transmission; and increases in new wells—more than twofold between 1973 and 1978—required numerous smaller compressors for gas gathering, as did the prohibition of flaring of waste gas (which now must be stored in tanks). Also, steep increases in capital expenditures of the coal mining industry—162 percent between 1958 and 1972 (after adjustment for price changes), and 169 percent between 1973 and 1977—indicate expansion in this industry's demand for compressors.

Expansion of petroleum pipeline capacity also raised the demand for pumps, particularly of the high-horsepower centrifugal kind, and for stationary compressors. While the network of petroleum pipelines operated by petroleum pipeline companies increased 16 percent between 1960 and 1970, and contracted somewhat thereafter, total oil transported rose 81 percent during the 1960's, and 48 percent in the 1970's.[8] At the same time, the average diameter of pipes was enlarged by one-third, roughly doubling capacity.[9] This required significant increases in the size and capacity of pumping equipment and compressors.

Expanding electrical generating capacity spurred the output growth especially of centrifugal pumps. These are used as boiler-feed pumps, as well as in many other operations requiring the circulation and condensation of steam and water. While the total number of electrical generating stations did not advance very much over the review period, the proportion of stations generating 500,000 kilowatts or more rose from under 3 percent in 1960 to 12 percent in 1979. Nuclear and gas-turbine driven, power-generating plants likewise increased. The rise in the number of larger electric generating plants spelled a shift to larger, more powerful pumps.[10]

Table 1. Productivity and related indexes for pump and compressor manufacturing, 1958–80

[1977 = 100]

Year	Output per employee hour	Output	Employee hours	Employees
1958	64.5	41.1	63.7	63.1
1959	68.8	43.4	63.1	62.6
1960	66.6	44.6	67.0	66.1
1961	69.2	43.9	63.4	62.6
1962	73.6	48.6	66.0	64.9
1963	78.1	51.7	66.2	64.6
1964	79.4	59.0	74.3	71.5
1965	80.9	65.2	80.6	77.9
1966	81.1	70.5	86.9	82.9
1967	82.5	70.1	85.0	82.4
1968	82.3	68.3	83.0	80.3
1969	86.3	74.0	85.7	83.3
1970	85.8	74.8	87.2	85.8
1971	87.1	69.4	79.7	79.4
1972	91.1	76.2	83.6	82.5
1973	97.8	87.7	89.7	86.6
1974	96.7	94.0	97.2	97.3
1975	91.3	87.0	95.3	96.0
1976	96.8	91.4	94.4	94.3
1977	100.0	100.0	100.0	100.0
1978	102.6	107.1	104.4	105.1

1980	99.8	112.9	113.1	113.9
Average annual rates of change (in percent):				
1958–80	2.1	4.7	2.6	2.7
1975–80	1.9	6.0	4.1	4.2

Construction accounts for another 18 percent of pump and compressor output. Centrifugal and trash pumps (which accommodate up to 25 percent of small solids in the water being pumped) are used in the clearing and preparing of construction sites.[11] Portable compressors are indispensable in the many pneumatical operations at construction sites. Between 1960 and 1973, the volume of total construction put in place rose at an average annual rate of 2.9 percent; thereafter it declined at a rate of 1.5 percent. However, some construction sectors with high demand for pumps continued to expand—for example, sewage system construction (spurred by more stringent environmental regulations).

Employment and hours

Employment in the pump and compressor manufacturing industry currently numbers approximately 91,000 persons. It rose 81 percent between 1958 and 1980, or at an average annual rate of 2.7 percent (compared with 1.1 percent for all manufacturing).

The long-term trend in employee hours in the industry did not differ significantly from the long-term trend in employment. They rose at a rate of 2.6 percent a year over the period, compared with 1.1 percent for manufacturing as a whole.

Production worker employment rose somewhat faster over the 1958–80 period than production workers' hours (2.7 percent a year versus 2.4 percent). Year-to-year changes ranged from an increase of 12 percent in 1974 to a decline of 10 percent for production worker employment; the range was wider still for hours. Overtime exceeded the manufacturing durables average in 17 of the 22 years examined here.[12] Comparatively high overtime hours were probably related to hiring and separation policies which, judging by the pertinent labor turnover data, have been such as to ensure retention of a relatively skilled work force. Labor turnover in the industry ran less than three-fifths of the manufacturing average for the period.[13] High overtime and low turnover rates were probably also related to the skill composition of the industry's work force.

Data on the skill composition of employees in pump and compressor manufacturing are not directly available. Such data have been compiled by the BLS only for the general industrial machinery group (SIC 356), of which pumps and compressors represent 29 percent by employment. Craft and related workers accounted for 30 percent of the production workers employed by establishments in this group in 1980, compared with 26 percent for total manufacturing. Metalworking craftworkers represented 12 percent of all production workers in the group, compared with 5 percent for manufacturing; and machinists 3 percent, compared with 1 percent. Operatives accounted for slightly more than three-fifths of all production workers in the general industrial machinery group, the same as in manufacturing as a whole. But metalworking operatives in industrial machinery, constituting one-third of production workers, had three times the share of their counterparts in all manufacturing. Laborers, with 6 percent of production workers in the group, had little more than half their share for all manufacturing.

Wage differentials also suggest a somewhat higher skill composition for production workers in pump and compressor establishments than in all manufacturing. In 1980, hourly earnings of the former ran 10 percent above the manufacturing average, and 3 percent above the manufacturing durables average. These ratios remained substantially unchanged during 1958–80. (Hourly earnings were about the same for production workers in the industry and in the general industrial machinery group of which the industry is part.)

Employment of nonproduction workers by pump and compressor manufacturing establishments rose at a slightly faster rate than that of production workers—2.9 percent a year (versus 2.7 percent). Nonproduction workers account for a comparatively high proportion of the industry's employment—41 percent in 1980, as against 30 percent for all manufacturing. The proportion did not change significantly over the review period. One of the reasons for the high proportion of nonproduction workers resides in the larger share accounted for by mechanical engineers in the industry groups' occupational makeup (the data are, again, for the general industrial machinery group). Such engineers represented 6 percent of all white-collar workers in the group in 1980—three times the comparable manufacturing ratio. Engineering and science technicians, among them drafters, made up 11 percent of white-collar workers in the group, as against 8 percent for manufacturing. The group also employed a somewhat higher proportion of clerical and secretarial workers (42 versus 40 percent). The share of blue-collar nonproduction workers, such as truckdrivers and service employees, was generally lower than for manufacturing.

Technological changes

Small lot production is the rule in pump and compressor establishments. Pumps and compressors are often large machines, manufactured to customer specification. While many of these machines are composed of standard parts, the economies associated with mass production are generally not available in producing pumps and compressors. The production process must constantly be adapted so as to cope with the many design, casting, and machining requirements that arise. Such adaptation was facilitated by the advent of numerically controlled machine tools in the 1960's, and the introduction of computer-aided design into engineering practice.[14] Numerical controls and computer-aided design have been important sources of labor productivity advances in the industry. The impact of these technological changes will be outlined, following a brief survey of the kinds and age of the metalworking machinery used in manufacturing pumps and compressors.

According to the *12th American Machinist Inventory of Metalworking Equipment* for 1976–78 (latest available), about one-third of all metal cutting and metal forming machine tools in the pump and compressor manufacturing industry were less than 10 years old; 70 percent were less than 20 years old. Comparable data for earlier years are available only for the general industrial machinery group (SIC 356). For general industrial machinery, no distinct trend in the age composition of metalworking machinery is observable. Thus, in 1958, 34 percent of such machinery installed in the plants of this group was less than 10 years old, 74 percent was less than 20 years. In 1968, as well as in 1978, the comparable figures read 33 and 72 percent.[15]

Despite the absence of a trend toward a more modern stock of metalworking equipment in terms of age, output capability per machine tool unit improved considerably. According to the *American Machinist's 10th Inventory of Metalworking Equipment* (1968), "For the last 5 years, the number of machine tools has increased by 4.5 percent, while the value of production, as measured in constant dollars by the *American Machinist* production index, has gone up by 39 percent." In the text accompanying its 12th Inventory (1976–78), the *American Machinist* again confirmed this trend. It noted that while the total machine tool "population" had declined by about one-tenth between 1968 and 1978, the production index had risen 40 percent.[16]

Machining time cut

The increase in the output capacity of machine tools has undoubtedly contributed to gains in the labor productivity of pump and compressor manufacturing. For example, machining time for pump casings, which often are of great weight and size, has in the leading plants been drastically reduced by specially designed milling machines. These milling machines also require less setup time, and a smaller number of setups than formerly. In one case, machining time for large centrifugal pump casings, weighing up to 18,000 pounds, was reduced from 48 to 17 employee hours; in other words, where three 16-hour shifts, involving two operators, were required earlier, only one operator working 17 hours is needed now.[17] However, electric energy requirements are considerably greater.[18]

Reductions in machining time are frequently achieved by combining in one large metalworking operation several previously separate ones. An example is the simultaneous milling, radial drilling, and facing (smoothing) of different parts of the same workpiece. Sequential operations on a given workpiece are speeded up by means of automatic tool changers, commanded by taped instructions, causing different kinds of tools (or different configurations of the same kind of tool) to be advanced, retracted, and changed, as programmed. (Such apparatus may be bypassed by manual controls, when necessary in the operator's judgment.)[19]

Reductions in setup time have also been made possible for many single-purpose machines, for example, grinders. Pump shafts must in some cases be tapered, and this has usually required several setups depending upon the length and desired fit of the shaft. In some of the industry's plants, separate setups for this purpose have been eliminated by grinders that adapt automatically and will grind several fits simultaneously.[20]

Table 2. Productivity and related indexes for pumps and pumping equipment manufacturing, 1972–80

[1977 = 100]

Year	Output per employee hour	Output	Employee hours	Employees
1972	90.8	81.0	89.2	88.1
1973	94.1	91.7	97.4	94.8
1974	93.6	91.9	98.2	98.3
1975	89.9	90.4	100.6	101.4
1976	92.7	92.9	100.2	99.7
1977	100.0	100.0	100.0	100.0
1978	101.1	106.1	104.9	106.2
1979	100.7	111.6	110.8	113.0
1980	97.2	112.5	115.8	117.6
Average annual rates of change (in percent):				
1972–80	1.2	3.9	2.6	3.1

Advances in the foundry operations of pump and compressor manufacturers have also contributed to labor productivity gains. In the technically more advanced plants, molding and coremaking have been speeded up by rapid-cycle machinery, and by discarding the time-consuming sand baking process. The no-bake process uses a resin binder and a catalyst to produce the sand mold, saving energy as well as unit labor requirements.[21] Several of the same core patterns (from which pump casings and other pump and compressor parts are cast) can be cut simultaneously by means of synchronous fabricating machinery, operating on the principle of key-making apparatus.

Engineering plays a key role in pump and compressor manufacturing. As noted, much of the industry's output is manufactured to customer specifications, which of necessity involves engineering staff. Additionally, the advent of numerically controlled machine tools, and of computer numerical controls, has centered more production responsibilities in engineering departments, away from the shop floor. The growth of engineering staff has intensified concern with promoting its efficiency. Engineering efficiency has been raised in the more advanced establishments of the industry by applying certain computer technologies; designing production processes which economize on engineering time; and standardizing common parts. Efforts have also been made to bypass engineering where feasible.[22]

Computer graphics have simplified drafting by allowing corrections to be made to the draft without manually redrawing it. Detailed drawings can be made within minutes, where before it took hours. Computerized data banks permit access to all drawings on file. Computer graphics has permitted the elimination of 7 to 8 drafter jobs in one of the establishments visited by BLS staff. The computer-aided design can be programmed directly upon tape, and fed to the machine tool. This represents a considerable advance for numerical controls, inasmuch as programs previously had to be punched, or prepunched programs had to be purchased.

With design and production closely linked, owing to the computer and numerical controls, engineers conceive of computer-aided design and computer-assisted manufacturing as integral operations. Calculation of formulae, design of the product, and production are viewed and operated as a single process. Uniformity of product dimension and quality are ensured. Changes in the detail of design are quickly and inexpensively incorporated. Engineering time saved by computer-aided design and computer-assisted manufacturing has been estimated at two-thirds of conventional engineering procedures.[23]

As noted, replacement of parts and attachments accounts for a sizable proportion of the output of pump and compressor manufacturing. Computer-aided design and computer-assisted manufacturing helps ensure that replacement parts are dimensionally accurate, while economizing on engineering time. Dimensional conformance is further ensured by certain process innovations. Thus, cores or molds for impellers and other pump and compressor components are now frequently ceramic instead of wood.

Capital expenditures

Plant and equipment outlays by pump and compressor manufacturers rose at an average annual rate of 8.1 percent between 1958 and 1980—compared with 4.9 percent per year for all manufacturing. (The expenditure data underlying these rates have been adjusted for price changes.[24]) The industry's capital spending rose at a particularly high rate during the 1960's, nearly tripling between 1958 and 1969. For a few years thereafter, such spending receded from the 1969 level, but it resumed its rise in 1972, and doubled between 1972 and 1980. Comparable figures for all manufacturing are considerably more modest, as the tabulation shows (average annual rates in percent):

	Pumps and compressors	*Manufacturing*
1958–80	8.1	4.9
1958–69	12.2	8.2
1969–80	6.9	4.6
1969–72 . .	-10.2	-3.0
1972–80 . .	7.6	5.4

Structure of the industry

In 1977, pumps and pumping equipment were manufactured in 613 establishments, air and gas compressors in 175. The former had increased 10 percent since 1972, the latter had more than doubled. In the preceding 9 years, no change in the number of establishments making pumps and compressors had occurred. The number of *companies* in the industry owning these establishments barely changed during the 1970's.[25]

Pumps and compressors are manufactured mostly in larger plants. Five percent of all establishments in the industry employed 45 percent of its workers in 1977, and accounted for about the same proportion of the total value of shipments. More generally, establishments with 100 workers or more represented less than one-quarter of the total number of establishments in the industry but well over four-fifths of total employment and value of shipments.

Table 3. Productivity and related indexes for air and gas compressor manufacturing, 1972–80

[1977 = 100]

Year	Output per employee hour	Output	Employee hours	Employees
1972	92.1	66.7	72.4	71.6
1973	106.8	79.8	74.7	76.6
1974	103.0	98.2	95.3	95.3
1975	96.7	80.5	85.0	85.3
1976	106.4	88.4	83.1	83.8
1977	100.0	100.0	100.0	100.0
1978	105.5	109.1	103.4	102.8
1979	106.0	120.3	113.5	112.2
1980	105.7	113.7	107.6	106.6
Average annual rates of change (in percent):				
1972–80	1.1	6.5	5.4	5.2

Concentration was high. The industry's four largest companies employed more than half of its workers in 1977, and accounted for half of its value of shipments. For manufacturing as a whole, the comparable ratios were 6 and 7 percent.

Even so, the establishments are mostly small, employing fewer than 100 persons. The smaller plants accounted for 79 percent (pumps) and 70 percent (compressors) of all industry establishments in 1977. At the same time, however, they recorded only 14 and 9 percent of total industry employment. These relationships had not changed much from earlier phases of the review period.

Outlook

Continued advances in the labor productivity of pump and compressor manufacturing are likely over the longer term. The diffusion of numerically controlled machine tools and computer-aided design within the industry's establishments, as well as among them, has still some way to go. The age distribution of metalworking machinery should continue to favor higher-capacity, modernized equipment. Organizational changes resulting from a widening scope of computer applications—for example, more centralized decisionmaking in reference to machining processes—will probably also improve productivity.[26]

So far, robots appear not to have been introduced widely. Even in the more advanced shops, they are used chiefly for paint spraying and other marginal operations. Industry observers, however, expect that robots, as their costs decline, will handle workpieces more and more during the noncutting portion of the work cycle.[27] Such a development is also bound to raise labor productivity.

The nearer-term outlook is somewhat clouded, however. The industry's output is likely to suffer from weakened demand from major users of pumps and compressors. When output slackens, a slowed rate of productivity advance, even declines in the rate, are more probable. A source of weakened demand is the stagnation in housing starts, which tends to diminish the need for pumps and compressors used in construction, as well as for such public works as water and sewage, which often require pumps and related equipment on a large scale. Another source of declining needs for (hence output of) pumps and compressors are reductions in projected increases in oilfield exploration and development. (These reductions have been linked to smaller-than-expected energy demand increases, and lessened price pressures.)[28]

At the same time, the widespread concern with cutting energy costs may bolster the demand (and output) of more energy-efficient pumps and compressors. For example, variable displacement pumps may to some extent replace fixed displacement pumps. The latter rejects excess flows by means of a relief valve, dumping them back into a reservoir. This wastes pump energy, which a variable displacement pump can avert.[29] Piston pumps, furthermore, are thought by industry observers to be also favored over fixed displacement pumps, as high-pressure hydraulics is more widely adopted in industry and transportation (especially in aircraft and mobile equipment). High-pressure hydraulics permits the use of lighter pipes, pumps, and actuators.[30]

Industry observers believe that pumps and equipment of larger size will continue to be installed in such uses as steampower generation, pipelines, and petroleum refining. The shift from gasoline to heavy fuel refining[31] requires heavier rotary rather than lighter centrifugal pumps. Slurry pipelines—which move water-suspended solids such as coal and wood chips—are believed to gain wider acceptance, because they offer important economies in transportation.

The BLS has projected a somewhat faster rise in the number of nonproduction workers than production workers for the general industrial machinery group.[32] In 1990, professional and technical workers will make up 12.4 percent of all of the group's employees, according to the projections, compared with 11.4 percent in 1980; and the share of clerical and related workers will rise slightly. The proportion of craftworkers will remain unchanged, and that of operatives will edge downward. It seems reasonable to assume that changes in occupational pattern projected for the general industrial machinery group will, by and large, be repeated by pump and compressor manufacturing. ☐

FOOTNOTES

[1] The pump and compressor manufacturing industry consists of two segments, pumps and pumping equipment, designated as SIC 3561 of the *Standard Industrial Classification Manual 1972* of the Office of Management and Budget; and air and gas compressors, SIC 3563. SIC 3561 consists of establishments primarily engaged in manufacturing pumps and pumping equipment for general industrial use. Measuring and dispensing pumps for gasoline stations are not included, nor are pumps installed in automobiles. SIC 3563 consists of establishments primarily engaged in manufacturing air and gas compressors for general industrial use. Refrigeration compressor units are not included. Prior to 1972, pumps and compressors were classified together in SIC 3561.

Average annual rates of change are based on the linear least squares of the logarithm of the index numbers. Extensions of the indexes will appear in the annual BLS Bulletin, *Productivity Measures for Selected Industries.*

Major Agreements Expiring Next Month

This list of collective bargaining agreements expiring in January is based on contracts on file in the Bureau's Office of Wages and Industrial Relations. The list includes agreements covering 1,000 workers or more.

Employer and location	Industry	Labor organization[1]	Number of workers
Associated Produce Dealers and Brokers of Los Angeles, Inc. (California)	Wholesale trade	Teamsters (Ind.)	2,200
Bunker Ramo Corp. (Illinois)	Electrical products	Electrical Workers (IBEW)	1,250
Campbell Soup Co. (Napoleon, Ohio)	Food products	Food and Commercial Workers	1,850
Caterpillar Tractor Co. (Joliet, Ill.)	Machinery	Machinists	5,700
Champion Spark Plug Co. (Interstate)	Electrical products	Auto Workers	4,300
Dana Corp., Spicer Axle Division (Fort Wayne, Ind.)	Transportation equipment	Allied Industrial Workers	2,300
Erwin Mills (North Carolina)	Textiles	Textile Workers	1,700
General Mills Fun Group, Inc., Kenner Products Division (Cincinnati, Ohio)	Miscellaneous manufacturing	Allied Industrial Workers	2,200
Greater Seattle Retail Drug Association, Inc. (Seattle, Wash.)	Retail trade	Food and Commercial Workers	2,500
Industrial Relations Council of Furniture Manufacturers in Southern California	Furniture	Carpenters	1,200
Johns-Manville Sales Corp. (Manville and Finderne, N.J.)	Stone, clay, and glass products	Paperworkers	1,550
Kelsey-Hayes Co. (Detroit and Romulus, Mich.)	Transportation equipment	Auto Workers	1,500
Kroehler Manufacturing Co. (Interstate)	Furniture	Upholsterers	1,100
Levingston Shipbuilding Co. (Orange, Texas)	Transportation equipment	Orange Metal Trades Council	1,700
Magic Chef, Inc. (Cleveland, Tenn.)	Fabricated metal products	Molders	1,250
Masonite Corp., Hardboard Division (Laurel, Miss.)	Lumber	Woodworkers	1,000
National Electrical Contractors Association, Inc., Western Pennsylvania Chapter	Construction	Electrical Workers (IBEW)	1,250
Philip Morris U.S.A. (Richmond, Va.)	Tobacco	Bakery, Confectionery and Tobacco Workers	7,200
Philip Morris U.S.A. (Louisville, Ky.)	Tobacco	Bakery, Confectionery and Tobacco Workers	2,450
R. H. Macy and Co., Inc., Bamberger Division (Newark, N.J.)	Retail trade	Food and Commercial Workers	1,800
Union Carbide Corp., Agricultural Products Co. (Institute, W. Va.)	Chemicals	Machinists	1,100
United Technologies Corp., Pratt and Whitney Aircraft Group, Government Products Division (West Palm Beach, Fla.)	Transportation equipment	Machinists	1,550

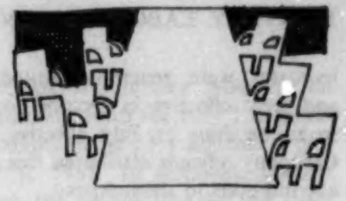
Developments in Industrial Relations



General Tire contract deviates from pattern

General Tire and Rubber Co. and the United Rubber Workers negotiated a 3-year contract for 1,200 workers in Waco, Tex., that deviated from the "pattern" settlement the union had negotiated with other major tire companies. (See *Monthly Labor Review*, July 1982, p. 53.) M.G. O'Neil, president and chairman of General Tire, said the new contract has "important implications for the whole of industry, not just the tire industry."

One of the changes from the pattern calls for skilled workers to receive larger quarterly cost-of-living pay adjustments than unskilled workers. O'Neil said this was necessary to counter a "compression" of pay rates between skilled and unskilled employees that had reduced the workers' incentive to stay in or move up to top-rated jobs, such as tire builder. The cost-of-living formula is the same as the pattern contract (quarterly adjustments of 1 cent an hour for each 0.26-point movement in the Consumer Price Index for Urban Wage Earners and Clerical Workers, CPI-W), except that only 60 percent of the payable amount will be distributed equally to all workers; the balance will be distributed as special adjustments to skilled workers. Another change from the pattern contract called for establishment of a profit-sharing plan that could increase the amount of money available for distribution under the cost-of-living pay adjustment formula.

In another move to relieve the pay compression, the parties reduced the pay rates for unskilled workers hired after the effective date of the contract. For example, the maximum rate for new janitors will be $8.63, compared with the $10.50 rate that still applies for janitors already on the payroll. The pay spread was further increased by providing immediate pay raises to skilled workers.

In the benefits area, the health insurance plan now requires employees to pay 10 percent of hospital room and board costs, up to a maximum of $400 for any one confinement. O'Neil said this would induce employees "to avoid going to the hospital or to shorten the stay."

The accord also revised the portion of the pension formula based on past service to $15 a month for each of the first 15 years of service, $16.50 for each of the next 15 years, and $17 a month for each year in excess of 30. All service accrued after the effective date of the agreement will be calculated at the $17 rate. The pattern settlement raised the benefit rate to $16.50 a month for each year of past or future service, from the $15 rate that prevailed at all of the tire companies, including General Tire.

Similar terms were accepted by 1,200 employees represented by the Rubber Workers at the company's Mayfield, Ky., plant.

Earlier in 1982, General Tire had closed a plant in Akron, Ohio (see *Monthly Labor Review*, June 1982, p. 65). During the current negotiations, the company indicated that the Waco plant also might be closed if the workers did not accept a moderate settlement.

Garment accord defers initial wage increase

About 70,000 workers in various locations were covered by a settlement between cotton garment manufacturers and the Clothing and Textile Workers. The accord deferred the initial wage increase of 25 cents an hour to January 1, 1983. The workers, who make shirts, pajamas, pants, and other garments, will also receive 30-cent increases on January 1 of 1984 and 1985. In addition, there is a provision for automatic cost-of-living pay adjustments in January of 1984 and 1985 equal to the percentage rise in the Consumer Price Index for Urban Wage Earners and Clerical Workers in excess of 5 percent during the preceding year. Each adjustment is limited to 10 cents an hour.

There also were improvements in benefits, including a 3-step increase in sickness and accident benefits to $105 a week, from $76.

Southern textile workers get wage increases

Several major textile mills in the South announced wage increases for their employees. The size of the increases was not divulged, except at Guilford Mills, which granted a 6-percent hike to 1,500 employees. The

---

"Developments in Industrial Relations" is prepared by George Ruben and other members of the staff of the Division of Developments in Labor-Management Relations, Bureau of Labor Statistics, and is largely based on information from secondary sources.

increases were generally limited to hourly employees and were effective in October or November, a change from the June or July effective dates in recent years. Company officials attributed this delay to poor economic conditions in the industry.

At Cannon Mills Corp., the wage increases for 20,000 employees were accompanied by improvements in insurance benefits and the addition of a paid holiday. Other companies granting increases were Burlington Industries, Inc. (38,000 employees affected), West Point Pepperell (15,000), Cone Mills, Inc., and Collins and Aikman.

Meanwhile, the Clothing and Textile Workers Union was bargaining on wages and benefits with Fieldcrest Mills, Inc., for approximately 7,000 workers. The union also was bargaining for smaller numbers of workers it represents at some operations of Cone Mills, Burlington, West Point Pepperell, and M. Lowenstein.

Martin Ward, president of Plumbers union, dies

Martin J. Ward, Jr., general president of the Plumbers and Pipefitters since 1971, died October 9 after a heart attack. Ward, 64, also was a vice president of the AFL-CIO, serving in a variety of assignments, but drawing particular praise for his efforts to further international cooperation among labor organizations.

Selected to succeed Ward was Marvin J. Boede, who had been assistant general president of the union since 1977. For the 2 preceding years, he had served as an international representative, assigned to the State of Michigan. Boede began his career as an official of the union in the 1960's after completing a plumbing apprenticeship.

Beef processor's workers call off strike

A bitter 4-month strike against Iowa Beef Processor's Dakota City, Neb., beef operations was ended when members of Local 222 of the United Food and Commercial Workers voted to return to work. An official of the local said that the return of the 1,600 workers was motivated by the economic hardships suffered by the strikers and by a belief that the union could strengthen its bargaining position by ending the walkout. The official said the union would continue to press the unfair bargaining practices charges it had filed against Iowa Beef, as well as its national boycott campaign against the company. There was no immediate indication of when talks would resume.

The walkout began in early June, after the parties had reached a bargaining stalemate. Reportedly, the union had been willing to accept a 2-year wage freeze, including a suspension of cost-of-living pay adjustments, similar to its earlier settlements with other meatpackers. (See *Monthly Labor Review*, February 1982, p. 48.) But, Iowa Beef was pressing for a 4-year pay freeze and for a $2-an-hour cut in pay for new workers, contending that its pay rates were higher than some the union had negotiated with competitive firms. According to the company, its minimum rates were $9.27 for workers in slaughtering, and $8.97 for those in processing.

Some picket line violence erupted when the company began hiring replacements for the strikers, and State police and the national guard were ordered to the scene by Iowa Governor Charles Thone. As the return to work was beginning, a union official commented, "I don't know what will happen to them [the replacements]. Obviously, there isn't room there for all of them."

GM, union set up occupational health panel

General Motors Corp. and the Auto Workers announced formation of a panel of six occupational health scientists to aid in improving workers' safety and health at the company. The new Occupational Health Advisory Board, headed by David W. Wegman of the Harvard School of Public Health, will evaluate and develop research projects, health programs, and related activities.

General Motors Vice President Alfred S. Warren, Jr. and Auto Workers Vice President Owen Bieber said the board is the first of its type established by a major industrial company and a union. The panel was established under terms of the 1982 collective bargaining settlement between the parties. (See *Monthly Labor Review*, May 1982, pp. 59–60.)

Second round of concessions at Hayes-Albion

About 470 workers at Hayes-Albion's Malleable Iron Division approved a second round of wage concessions in an effort to avert a shutdown of the 93-year-old plant, located in Albion, Mich. In addition to a $1.16 cut in their $10.38 an hour average pay, they agreed to a freeze on cost-of-living pay adjustments and a reduction in paid holidays, insurance, and other benefits. The employees are represented by the United Auto Workers.

Despite the 3-year concession agreement, the company did not guarantee that the foundry would remain open, noting that it was operating at only 30 percent of capacity and had suffered losses in each of the last 3 years. The company had been forced to close two other plants in Tiffin and Bryan, Ohio.

In a related development, the Albion city council moved to aid the company by granting it 3 months of free water and sewer service valued at about $31,000. The city government also was proceeding with efforts to have local businesses help ease the impact of the cuts at the plant by holding down or reducing their prices.

Concession agreement at Rockwell International

Workers at Rockwell International Corp. agreed to a concession agreement that supersedes a contract scheduled to expire in February 1983. About 5,200 workers at 10 heavy-vehicle parts plants were covered by the new contract, which runs to July 19, 1985. Reportedly, terms included no specified wage increases, an 18-month deferral of each of the next three usual quarterly cost-of-living pay adjustments, and a 25-percent reduction in the size of all subsequent adjustments. In return, the company agreed to advance money to the weakened Supplemental Unemployment Benefits fund and to increase its basic financing rate. The company also increased certain other benefits for workers affected by layoffs and plant closings.

About half of the members of the Auto Workers union affected by the settlement are on layoff. The plants are located in Michigan, Illinois, Indiana, Ohio, and Kentucky.

Union initiates concessions to save jobs

In Tecumseh, Mich., workers at Tecumseh Products Co. voted to freeze their cost-of-living pay allowance for 1 year. This precluded payment of a 20-cent-an-hour increase in the allowance that had been scheduled for the beginning of October.

According to Raymond R. Jackson, president of the independent United Products Workers Union, the move was initiated by the union. He said the plant was currently shut down for 3½ weeks because of a lack of orders for the automotive air conditioning compressors it produces. Current employment at the plant is 560 workers, compared with 1,400 in recent years and 3,400 in 1968.

Bargaining completed for city employees

Bargaining between the City of New York and its employees was essentially completed in mid-October when 35,000 uniformed employees agreed on 2-year contracts. In September, the city had settled with a coalition of 40 unions representing 180,000 nonuniformed employees.

In the wake of these settlements, the only employees still bargaining with the city were 7,300 sanitation workers, and small groups of uniformed supervisory police officers.

Mayor Edward Koch acknowledged that the settlement for the uniformed police patrol officers, firefighters, and correction officers was more liberal than that for the nonuniformed employees. But, he explained, this was proper because the uniformed employees "perform the most dangerous work of all our city employees." The uniformed employees contracts called for an 8-percent pay increase retroactive to the July 1 termination date of the prior contracts, and for another 8 percent increase on July 1, 1983. In addition, current employees who were on the payroll during the city's 1975–76 fiscal crisis will receive a $988 payment to repay wages that were lost when all of the city's unions agreed to a 1-year suspension of part or all of a 6-percent wage increase that was effective July 1, 1975. Payment was to be spread over a period of years. Other contracts terms included improvements in health insurance benefits and a $200 increase in longevity pay. Prior to the settlement, the top base pay for employees in all three groups had been $23,519 after 3 years of service.

The unions involved in bargaining for uniformed employees were the Patrolmen's Benevolent Association, the Uniformed Firefighters Association, the Correction Officers Benevolent Association, the Uniformed Fire Officers Association, and the Housing Patrolmen's Benevolent Association.

The accord for 180,000 nonuniformed workers called for a 2-year term generally beginning July 1, 1982. However, the initial wage increase of 8 percent was delayed 2 months for most of the employees. The agreement also provided for increased city financing of health insurance and other benefits.

Earlier in the year, 35,000 New York City bus and subway workers were affected by a 3-year arbitration award that ended a bargaining impasse between the Transport Workers and Amalgamated Transit Workers unions and the Metropolitan Transit Authority. The award provided for a 7-percent pay increase retroactive to the April 1, 1982, termination date of the prior contracts, and for increases of 6 percent on April 1, 1983, 4 percent on April 1, 1984, and 3 percent on July 1, 1984. The award also terminated the automatic cost-of-living pay adjustment provision; added an 11th paid holiday; and increased the transit authority's financing of health and welfare benefits. The transit authority is a State agency.

Teacher settlements

The start of the new school year was accompanied by a number of settlements for public school teachers and related employees.

- In Detroit, 11,000 teachers represented by the American Federation of Teachers were covered by a 1-year contract that did not provide for a salary increase. The settlement was preceded by a 3-week strike.
- In Philadelphia, 20,000 teachers represented by the American Federation of Teachers were covered by a 3-year contract that called for 6 percent salary increases in September 1982 and March of 1984 and

1985. The school board also agreed to finance 80 percent of health and welfare benefits (up from 60 percent), and to pay the teachers for time lost during their 1981 strike—10 days of pay immediately and 9 days at retirement.

- In Chicago, 30,000 members of the American Federation of Teachers agreed to a 1-year contract that did not provide for salary or benefit improvements. The school board did agree to continue paying the full cost of pensions; prior to the 1981 settlement, the teachers had contributed 7 percent of their salary. The teachers gave up 1 day of pay to help minimize the cost of the 1982 settlement.
- In Jefferson County, Ky., 5,200 members of the National Education Association were covered by a 2-year agreement that provided for a 5.3-percent salary increase effective July 1, 1982, and a 4.7-percent increase effective July 1, 1983. The accord also called for a .5-percent (of salary) increase in employer financing of benefits, and increment increases of $500 for teachers with 20 years of service and $1,000 for those with 25 years of service.
- In Seattle, 2,500 members of the National Education Association were covered by a 1-year accord that did not provide for salary or benefit improvements.
- In Newark, N.J., 5,500 teachers represented by the American Federation of Teachers were covered by a 3-year contract that provided for a 6-percent salary increase retroactive to July 1 and for 8-percent increases on July 1 of 1983 and 1984. Teachers with 20 years of service receive $684 a year in longevity pay, increasing to $739 on July 1, 1983, and $798 on July 1, 1984.
- In Florida, 6,400 members of the independent Hillsborough (County) Classroom Teachers Association were covered by a 1-year contract that provided for an 8.5-percent salary increase. Other terms included complete financing of health benefits by the school board, as long as premiums do not increase more than 30 percent (teachers previously paid part of the premium), full payment for unused sick leave at retirement (formerly 75 percent); and up to 7 years of credit for full-time teaching outside the county (formerly 5 years).

Howard Johnson's to pay overtime wages

Two years of legal proceedings against the Howard Johnson's motel and restaurant chain ended when the firm agreed to pay $5 million in overtime wages to 5,000 current and former employees. The U.S. Department of Labor had charged that the company violated the Fair Labor Standards Act by not paying time-and-a-half rates for work in excess of 40 hours a week by salaried manager trainees and assistant managers earning under $250 a week, and hourly paid managers and manager trainees.

During the proceedings, Howard Johnson's contended the employees were exempt from the overtime pay requirements because they were part of "management." The Department maintained this was incorrect because the workers earned less than $250 a week, and because its investigation showed that they spent more than 40 percent of their time in "routine, non-management" type work.

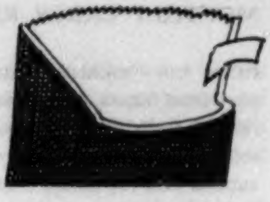
The $5 million will be distributed to current and former employees who performed in the jobs from August 1977 to March 1982. The settlement involved workers at 900 locations. Money that the company is unable to distribute because it cannot locate former employees will be paid into the U.S. Treasury.

Union leadership changes

In a November election, 33-year-old challenger Rich Trumka defeated Sam Church for the presidency of the United Mine Workers. The vote margin was about 2 to 1. However, Church did not concede the results, continuing to press his claim that Trumka had not served the required 5 years in the mines. Trumka, who had been a UMW staff attorney after working in the mines, said his priorities were to speed up organizing efforts to reverse the decline in the percentage of coal mined by the union's members, increase local political activity to help win legal objectives, and improve internal finances. The UMW has about 220,000 members—120,000 actively employed, 40,000 on layoff, and 60,000 retirees.

At the Auto Workers, the union's executive board backed Owen Bieber to succeed Douglas Fraser when he retires in May 1983. Fraser, who is leaving because he is at the union's mandatory retirement age of 65, has guided the union for 6 difficult years during which its members were hard hit by layoffs and contract concessions resulting from the domestic automobile industry's difficulties. Bieber, age 52, began his career in the industry in 1948 in Michigan, then moved through a succession of local, regional, and national jobs in the union. Since 1980, he has been a vice president of the UAW and has headed its General Motors Department. Bieber's accession to the presidency of the UAW was expected to be ratified at its May 1983 convention. ☐

Book Reviews



Help wanted—for women resuming careers

Women Returning to Work: Policies and Progress in Five Countries. Edited by Alice M. Yohalem. Montclair, N.J., Allanheld, Osmun & Co. Publishers, Inc., 1980. 292 pp. $25.

In recent decades, industrialized nations have experienced substantial growth in labor force participation by women. The value of this comparative international study lies in its cumulative effect, in its delineation of the almost universal cultural and political framework underlying the employment aspirations and opportunities of these women. The study grew out of the interest of the German Marshall Fund in sponsoring research on the changing role of women in advanced industrial nations. Financed by a Federal grant, the study was carried out with the cooperation of the Conservation of Human Resources Project, Columbia University.

Participants in the cross-national study (West Germany, France, the United Kingdom, Sweden, and the United States) met in 1978 to discuss the key areas to be investigated. With allowance for variances of statistical data, each national study sought to provide data on the number of women reentrants to the labor force; their specific problems on reentry; governmental policies regarding reentrants, especially in the context of labor market policy (but also, in some studies, with reference to incentives and disincentives created by taxation and family assistance policies); finally, each author's recommendations on facilitating reentry of women. Each national study presents relevant legislation and available statistical data, supplemented by quotations obtained in interviews with reentrants.

An underlying premise of the studies is that women in industrial economies will spend a good portion of their lives in the paid labor force. Several factors—including smaller families, inflationary pressures, the rise in the numbers of divorces and families headed by women—now lead to the conclusion that the average woman is likely to spend two decades or more in the labor force, and, therefore, opportunities and encouragement should be given to young women for greater education and training. For each country, the studies address two basic questions: (1) Do government labor market policies encourage participation by women returning to the labor force by providing equal access to needed counseling; training; child care; unemployment or subsistence benefits; sponsored public employment programs; options for part-time and full-time employment? (And, in some studies, do tax and family-benefit policies on balance encourage such women to reenter the labor force?) (2) What alternative government policies might better facilitate the reentry of such women?

In an excellent foreword, Eli Ginzberg, director of the Conservation of Human Resources Project, sums up the individual study findings relative to the first question:

> Despite significant differences in attitudes and behavior toward the return of mature women to work, France, Germany and the United Kingdom demonstrate several elements in common. Each of these countries gives priority in practice to programs for unemployed and unskilled youth and adult males and to persons seeking upgrading in skills in high demand. Such programs usually offer benefits that include compensation for earnings loss, social insurance coverage, travel expenses, and household maintenance. Facilitating the reentry of adult women is not deemed worthy of special assistance. Despite increases in the work activity of adult women in these nations, they are still regarded as a peripheral labor supply that can be adjusted to fluctuations in demand. Together with policies aimed at opening and closing the flow of guest workers, women remain the major balance wheel. . . . Although the United States has established a series of measures to promote equal employment opportunity, they are not the equivalent of the national commitment to equality in all social relationships that underlies the Swedish model.

These generalizations are supported by findings of the individual studies. Day care is insufficient for needs, especially for older children, and priority is given to those women already working, or receiving public funds, or heading families. In France, the National Employment Agency (ANPE) is "absolutely snowed under" by requests from "men, young people and people suddenly out of work" and thus placement personnel and counselors "are a bit negligent in helping reentrants who are reputedly difficult to place" even though, "since 1978, training programs are rightfully open to (them)." For West Germany, although the 1969 Labor Promotion Act explicitly covers women reentrants as a target group, the current policy is to measure the potential labor force as including the "silent reserve" during boom times, but "excluding the silent reserve and registered part-time female job-seekers, primarily returnees, during recessions." "No statistics have been published on the role of participation by women returnees in the advanced and retraining measures, although the act specifically provides for them." Training benefits are conditional upon extensive prior and subsequent employment, often inconsistent with women's family obligations; subsistence benefits are lower for women because their labor force participation is generally classified as "desirable" rather than "necessary." With statistical data lacking, the author assumes that the "labor exchange is negatively selective in regard to women" (in publicly funded employment) because most women returnees are not benefit-recipients, and their unemployment represents no drain on public funds. In the United Kingdom, the Manpower Services Commission has "until recently tended to resist provision for special sections of the population," although the 1973 Employment and Training Act encouraged the Commission to include arrangements for increasing the opportunities for women and girls for employment and training. In the United States, measures to achieve "maximum employment" are endorsed by the Full Employment and Balanced Growth Act of 1978, but in the interest of controlling inflation, structural remedies (such as the Comprehensive Employment and Training Act, CETA) have in recent years been the dominant method of dealing with unemployment. In such programs, a study by Wharton School faculty members (O. R. Perry and others, *The Impact of Government Manpower Programs in General and on Minorities and Women,* University of Pennsylvania, Wharton School, 1975) found that minority and female trainees were heavily concentrated in programs having a limited emphasis on the acquisition and development of marketable occupational skills. "Only in the late 1970's have certain reentrants been specifically identified in legislation as targets for special types of assistance." And "some programs which have been especially designed for displaced homemakers" [often build] "on competencies gained in housekeeping and child rearing."

Only Sweden appears to have made serious effort to promote the full integration of returning women into the labor force. An Advisory Council on Equality between Men and Women was appointed in 1972, with prime emphasis on "unemployed and untrained women"—often synonymous with reentering women. Even so, cultural patterns, as well as the growing demand of the public sector fields (education, health, child and elderly care), have directed women reentrants and newcomers alike to employment in traditional "women's fields." In Sweden, as elsewhere, women continue to accept the main responsibility for home and child care, and occupy 91 percent of part-time jobs.

With respect to taxation policies and family income subsidies, those studies which dealt with this aspect emphasized the disincentives to full labor market participation by married women, or those with children. Some changes have been made to improve incentives. For example, in Sweden, a system of individual taxation was adopted in 1971 in place of the former high marginal tax on the wife's earnings; in the United States, the 1981 tax revisions also moderated the "marriage tax." The low pay for most "women's jobs" creates a policy dilemma: public funds can provide a higher standard of living for the family than can an unskilled female worker, whose net employment income may be negative after the loss of food, housing, and medical benefits associated with public assistance.

Recommendations by each author for improvement in the treatment of reentry women differ in emphasis, depending on each national situation. However, in general, the studies stress improved data collection and publication. (The United States compares favorably with other countries in this respect, but even more data are needed here also.) The recommendations also urge elimination of sex-stereotypes in education and vocational training, not only so that mature women may have access to better-paid "men's jobs," but also so that young women will not be led by social pressures to abandon schooling too soon, or to focus only on "women's fields." Other recommended governmental measures include an even-handed policy for both sexes by public employment agencies relative to counseling, training, unemployment and subsistence grants, and provision of public sector jobs; explicit governmental encouragement of equal parental responsibility for children and improved legislation regarding leave for parental duties; and public funding of high-quality child care for those families choosing to make use of such facilities. Such costly measures are unlikely to be adopted by governments facing periods of depressed economic growth. Therefore, it was also recommended that governments foster economic growth to the extent necessary to provide full employment, and thus improve job opportunities for all, including female reentrants.

This collection of studies will be highly useful to governmental policymakers as a means of measuring comparative progress in fostering the welfare of female citizens, as well as comparative success in fully utilizing labor resources. The authors bring to the present volume a record of significant studies of women in the labor market. A few minor criticisms may be noted: The quotations from interviews add immediacy, but there is no indication of interview format. In a few instances, sources of numerical data are not clearly spelled out. Nevertheless, all interested researchers will welcome these documented studies.

In the reviewer's opinion, this collection of studies, by revealing the near-universality of the constraints faced by female reentrants, also strengthens the case for major reform of the educational system in order to modify societal biases. It is likely that the number of "reentrants" will diminish in the coming decades, as work force continuity of women becomes more like that of men. But the persistent problems of women in the labor force, of holding mostly low-pay, dead end jobs, will not be diminished until the educational system is made responsive to the new lifetime commitment of women to the paid labor force. In reference to the eligibility for skill training in the United Kingdom, the author writes: . . . "females tend to miss out twice—as girls 'because they will soon leave and have a baby,' and as reentrants because they are beyond the age for trainees and have not had the experience to justify further training." The distinctions in primary and secondary schools in academic curricula, physical education, and vocational training are extended and worsened in post-secondary training and college and university selection processes at undergraduate, graduate, and professional levels. The 30- to 50-year-old returnee who needs confidence-building, counseling, and job-readiness programs is the predictable product of a societal system which during the educational process considers her chiefly in relation to her child-rearing years, but then subsequently hands back to each woman the problems of belatedly acquiring the education or training needed for economic survival while juggling work schedules and children's needs.

Managerial perfection

The Transactional Manager: How to Solve People Problems with Transactional Analysis. By Abe Wagner. Englewood Cliffs, N.J., Prentice Hall, Inc., 1981. 196 pp., bibliography. $11.95.

Abe Wagner suspects that many supervisors and managers attain their positions based on the "Peter Principle," whereby their technical prowess is rewarded by putting them in charge of people, but lacking communication skills they become ineffective in their dealings with those they manage. The author's answer to the above problem is the gist of this book. He states that he has simplified and recast some of the transactional analysis theory developed by psychiatrist Eric Berne "to make it more readily useful to people who are unfamiliar with transactional analysis." The manager absorbs this material, applies it to his or her own behavior, avoiding any use of it for coercive or manipulative purposes, and develops those communication skills, or the author's preference, "people skills," to create more effective and productive managerial qualities.

Over the past decade, there have been at least 10 books published which are aimed at the manager, salesperson, personnel officer, and so on, all indicating that by learning, and then applying the techniques of transactional analysis, they can greatly improve the efficacy of their occupational work as they relate to and with others. It's very hard to disagree with the bare bones of such a proposition—people who are highly self-aware, in charge of their own behavior, and able to model rational behavior before others (the elements of transactional analysis) will generally have a more successful working and personal life than those lacking such attributes—but that's not the basic question in this book. The real question is: Can a person by *reading* a book actually internalize the contents to the point of *changing* his or her behavior? Knowledge *about* something, which comes from reading or attending lectures, gives a person an intellectual storehouse of ideas, but it is entirely different from knowledge of *experience,* which comes from actually having existed in the interpersonal situations, good or bad, which transactional analysis theory and guidelines attempt to articulate.

This book is lucid and to the point. Wagner explicates without overreliance on jargon and speaks to those who have some background in psychoanalytical theory out of which Berne evolved the transactional analysis formulations. To others, this book may be an incentive to look further into their personal behavior. But to believe that a book, even as good as this one, can help promote a move toward managerial reformation is an overoptimistic piety.

To be sure, at the end of the book, Wagner suggests that a consultant in transactional analysis may be needed to incorporate the idea of improved "people skills" within an organization, and some companies have apparently tried this with varying outcomes. However, managers in either the private or the public sector may, for the most part, be shocked by the author's opinion that they might benefit from personal therapy as a step in changing their own behavior, because again, the opinion is an intellectual construct, however valid it may be, and not a self-realization from an actual experience. This book deals a bit too lightly in the serious matters it so adequately describes and thus raises additional questions about its ultimate acceptance by the managers it seeks to attract.

34. Effective wage adjustments in collective bargaining units covering 1,000 workers or more, 1977 to date 93

Work stoppage data. Definition 94
35. Work stoppages involving 1,000 workers or more, 1947 to date 94

NOTES ON CURRENT LABOR STATISTICS

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics. A brief introduction to each group of tables provides definitions, notes on the data, sources, and other material usually found in footnotes.

Readers who need additional information are invited to consult the BLS regional offices listed on the inside front cover of this issue of the *Review*. Some general notes applicable to several series are given below.

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might otherwise mask short-term movements of the statistical series. Tables containing these data are identified as "seasonally adjusted." Seasonal effects are estimated on the basis of past experience. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years.

Seasonally adjusted labor force data in tables 2–7 were revised in the March 1982 issue of the *Review* to reflect experience through 1981. The original estimates also were revised to 1970 to reflect 1980 census population controls.

Beginning in January 1980, the BLS introduced two major modifications in the seasonal adjustment methodology for labor force data. First, the data are being seasonally adjusted with a new procedure called X-11/ARIMA, which was developed at Statistics Canada as an extension of the standard X-11 method. A detailed description of the procedure appears in *The X-11 ARIMA Seasonal Adjustment Method* by Estela Bee Dagum (Statistics Canada Catalogue No. 12-564E, February 1980). The second change is that seasonal factors are now being calculated for use during the first 6 months of the year, rather than for the entire year, and then are calculated at mid-year for the July-December period. Revisions of historical data continue to be made only at the end of each calendar year.

Annual revision of the seasonally adjusted payroll data shown in tables 10, 12, and 14 were made in August 1981 using the X-11 ARIMA seasonal adjustment methodology. New seasonal factors for productivity data in tables 28 and 29 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month to month and from quarter to quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of $3 and a current price index number of 150, where 1967 = 100, the hourly rate expressed in 1967 dollars is $2 ($3/150 × 100 = $2). The resulting values are described as "real," "constant," or "1967" dollars.

Availability of information. Data that supplement the tables in this section are published by the Bureau of Labor Statistics in a variety of sources. Press releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule given below. The *BLS Handbook of Labor Statistics*, Bulletin 2070, provides more detailed data and greater historical coverage for most of the statistical series presented in the *Monthly Labor Review*. More information from the household and establishment surveys is provided in *Employment and Earnings*, a monthly publication of the Bureau. Historically, comparable information from the establishment survey is published in two comprehensive data books—*Employment and Earnings, United States* and *Employment and Earnings, States and Areas*, and their annual supplements. More detailed information on wages and other aspects of collective bargaining appears in the monthly periodical, *Current Wage Developments*. More detailed price information is published each month in the periodicals, the *CPI Detailed Report* and *Producer Prices and Price Indexes*.

Symbols

p = preliminary. To improve the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.
r = revised. Generally, this revision reflects the availability of later data but may also reflect other adjustments.
n.e.c. = not elsewhere classified.

Schedule of release dates for major BLS statistical series

Series	Release date	Period covered	Release date	Period covered	MLR table number
Employment situation	December 3	November	January 7	December	1–10
Producer Price Index	December 10	November	January 14	December	21–25
Consumer Price Index	December 21	November	January 21	December	17–20
Real earnings	December 21	November	January 21	December	11–15
Productivity and costs:					
Nonfinancial corporations	.....	....	....	....	26–29
Nonfarm business and manufacturing	.....	....	January 28	4th quarter	26–29
Major collective bargaining settlements	.....	....	January 31	1982	33–34

EMPLOYMENT DATA FROM THE HOUSEHOLD SURVEY

EMPLOYMENT DATA in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 60,000 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons are (1) those who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work because they were on layoff or waiting to start new jobs within the next 30 days are also counted among the unemployed. The **unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **civilian labor force** consists of all employed or unemployed persons in the civilian noninstitutional population; the **total labor force** includes military personnel. Persons **not in the labor force** are those not classified as employed or unemployed; this group includes persons retired, those engaged in their own housework, those not working while attending school, those unable to work because of long-term illness, those discouraged from seeking work because of personal or job market factors, and those who are voluntarily idle. The **noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy.

Full-time workers are those employed at least 35 hours a week; **part-time workers** are those who work fewer hours. Workers on part-time schedules for economic reasons (such as slack work, terminating or starting a job during the week, material shortages, or inability to find full-time work) are among those counted as being on full-time status, under the assumption that they would be working full time if conditions permitted. The survey classifies unemployed persons in full-time or part-time status by their reported preferences for full-time or part-time work.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the preceding years. These adjustments affect the comparability of historical data presented in table 1. A description of these adjustments and their effect on the various data series appear in the Explanatory Notes of *Employment and Earnings.*

Data in tables 2-7 are seasonally adjusted, based on the seasonal experience through December 1981.

1. Employment status of the noninstitutional population, 16 years and over, selected years, 1950-81

[1] The population and Armed Forces figures are not seasonally adjusted.

[2] Civilian employment as a percent of the total noninstitutional population (including Armed Forces).

NOTE: Detail for the above race and Hispanic-origin groups will not sum to totals because data for the "other races" group are not presented and Hispanics are included in both the white and black population groups.

3. Selected employment indicators, seasonally adjusted

EMPLOYMENT, HOURS, AND EARNINGS DATA FROM ESTABLISHMENT SURVEYS

EMPLOYMENT, HOURS, AND EARNINGS DATA in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by 177,000 establishments representing all industries except agriculture. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

Definitions

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in manufacturing include blue-collar worker supervisors and all nonsupervisory workers closely associated with production operations. Those workers mentioned in tables 11–15 include production workers in manufacturing and mining; construction workers in construction; and nonsupervisory workers in transportation and public utilities; in wholesale and retail trade; in finance, insurance, and real estate; and in services industries. These groups account for about four-fifths of the total employment on private nonagricultural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W). The **Hourly Earnings Index** is calculated from average hourly earnings data adjusted to exclude the effects of two types of changes that are unrelated to underlying wage-rate developments: fluctuations in overtime premiums in manufacturing (the only sector for which overtime data are available) and the effects of changes and seasonal factors in the proportion of workers in high-wage and low-wage industries.

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received and are different from standard or scheduled hours. **Overtime hours** represent the portion of gross average weekly hours which were in excess of regular hours and for which overtime premiums were paid.

Notes on the data

Establishment data collected by the Bureau of Labor Statistics are periodically adjusted to comprehensive counts of employment (called "benchmarks"). The latest complete adjustment was made with the release of May 1982 data, published in the July 1982 issue of the *Review*. Consequently, data published in the *Review* prior to that issue are not necessarily comparable to current data. Complete comparable historical unadjusted and seasonally adjusted data are published in a Supplement to Employment and Earnings (unadjusted data from April 1977 through February 1982 and seasonally adjusted data from January 1974 through February 1982) and in *Employment and Earnings, United States, 1909–78*, BLS Bulletin 1312–11 (for prior periods).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20. See also *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976).

NOTE: The industry divisions of mining; construction; tobacco manufactures (a major manufacturing group, nondurable goods); transportation and public utilities; and finance, insurance, and real estate are no longer shown. This is because the seasonal component in these is small relative to the trend-cycle, or irregular components, or both, and consequently cannot be precisely separated.

UNEMPLOYMENT INSURANCE DATA

NATIONAL UNEMPLOYMENT INSURANCE DATA are compiled monthly by the Employment and Training Administration of the U.S. Department of Labor from monthly reports of unemployment insurance activity prepared by State agencies. Railroad unemployment insurance data are prepared by the U.S. Railroad Retirement Board.

Definitions

Data for **all programs** represent an unduplicated count of insured unemployment under State programs, Unemployment Compensation for Ex-Servicemen, and Unemployment Compensation for Federal Employees, and the Railroad Insurance Act.

Under both State and Federal unemployment insurance programs for civilian employees, insured workers must report the completion of at least 1 week of unemployment before they are defined as unemployed. Persons not covered by unemployment insurance (about 10 percent of the labor force) and those who have exhausted or not yet earned benefit rights are excluded from the scope of the survey. **Initial claims** are notices filed by persons in unemployment insurance programs to indicate they are out of work and wish to begin receiving compensation. A claimant who continued to be unemployed a full week is then counted in the insured unemployment figure. The **rate of insured unemployment** expresses the number of insured unemployed as a percent of the average insured employment in a 12-month period.

An **application** for benefits is filed by a railroad worker at the beginning of his first period of unemployment in a benefit year; no application is required for subsequent periods in the same year. **Number of payments** are payments made in 14-day registration periods. The **average amount of benefit payment** is an average for all compensable periods, not adjusted for recovery of overpayments or settlement of underpayments. However, **total benefits** paid have been adjusted.

[1] Initial claims and State insured unemployment include data under the program for Puerto Rican sugarcane workers.

[2] Excludes transition claims under State programs.

[3] Excludes data on claims and payments made jointly with other programs.

[4] Excludes data on claims and payments made jointly with State programs.

[5] Cumulative total for fiscal year (October 1-September 30). Data computed quarterly.

NOTE: Data for Puerto Rico and the Virgin Islands included. Dashes indicate data not available.

r=revised.

p=preliminary.

PRICE DATA

PRICE DATA are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period (1967 = 100, unless otherwise noted).

Definitions

The **Consumer Price Index** is a monthly statistical measure of the average change in prices in a fixed market basket of goods and services. Effective with the January 1978 index, the Bureau of Labor Statistics began publishing CPI's for two groups of the population. One index, a new CPI for All Urban Consumers, covers 80 percent of the total noninstitutional population; and the other index, a revised CPI for Urban Wage Earners and Clerical Workers, covers about half the new index population. The All Urban Consumers index includes, in addition to wage earners and clerical workers, professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctor's and dentist's fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items is kept essentially unchanged between major revisions so that only price changes will be measured. Prices are collected from over 18,000 tenants, 24,000 retail establishments, and 18,000 housing units for property taxes in 85 urban areas across the country. All taxes directly associated with the purchase and use of items are included in the index. Because the CPI's are based on the expenditures of two population groups in 1972–73, they may not accurately reflect the experience of individual families and single persons with different buying habits.

Though the CPI is often called the "Cost-of-Living Index," it measures only price change, which is just one of several important factors affecting living costs. Area indexes do not measure differences in the level of prices among cities. They only measure the average change in prices for each area since the base period.

Producer Price Indexes measure average changes in prices received in primary markets of the United States by producers of commodities in all stages of processing. The sample used for calculating these indexes contains about 2,800 commodities and about 10,000 quotations per month selected to represent the movement of prices of all commodities produced in the manufacturing, agriculture, forestry, fishing, mining, gas and electricity, and public utilities sectors. The universe includes all commodities produced or imported for sale in commercial transactions in primary markets in the United States.

Producer Price Indexes can be organized by stage of processing or by commodity. The stage of processing structure organizes products by degree of fabrication (that is, finished goods, intermediate or semifinished goods, and crude materials). The commodity structure organizes products by similarity of end-use or material composition.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States, from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

In calculating Producer Price Indexes, price changes for the various commodities are averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1972. The detailed data are aggregated to obtain indexes for stage of processing groupings, commodity groupings, durability of product groupings, and a number of special composite groupings.

Price indexes for the output of selected SIC industries measure average price changes in commodities produced by particular industries, as defined in the *Standard Industrial Classification Manual 1972* (Washington, U.S. Office of Management and Budget, 1972). These indexes are derived from several price series, combined to match the economic activity of the specified industry and weighted by the value of shipments in the industry. They use data from comprehensive industrial censuses conducted by the U.S. Bureau of the Census and the U.S. Department of Agriculture.

Notes on the data

Beginning with the May 1978 issue of the *Review*, regional CPI's cross classified by population size, were introduced. These indexes will enable users in local areas for which an index is not published to get a better approximation of the CPI for their area by using the appropriate population size class measure for their region. The cross-classified indexes will be published bimonthly. (See table 19.)

For further details about the new and the revised indexes and a comparison of various aspects of these indexes with the old unrevised CPI, see *Facts About the Revised Consumer Price Index*, a pamphlet in the Consumer Price Index Revision 1978 series. See also *The Consumer Price Index: Concepts and Content Over the Years*, Report 517, revised edition (Bureau of Labor Statistics, May 1978).

For interarea comparisons of living costs at three hypothetical standards of living, see the family budget data published in the *Handbook of Labor Statistics, 1977*, Bulletin 1966 (Bureau of Labor Statistics, 1977), tables 122–133. Additional data and analysis on price changes are provided in the *CPI Detailed Report* and *Producer Prices and Price Indexes*, both monthly publications of the Bureau.

As of January 1976, the Wholesale Price Index (as it was then called) incorporated a revised weighting structure reflecting 1972 values of shipments. From January 1967 through December 1975, 1963 values of shipments were used as weights.

For a discussion of the general method of computing consumer, producer, and industry price indexes, see *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976), chapters 13–15. See also John F. Early, "Improving the measurement of producer price change," *Monthly Labor Review*, April 1978, pp. 7–15. For industry prices, see also Bennett R. Moss, "Industry and Sector Price Indexes," *Monthly Labor Review*, August 1965, pp. 974–82.

17. Consumer Price Index for Urban Wage Earners and Clerical Workers, annual averages and changes, 1967–81

[1] Data for June 1982 have been revised to reflect the availability of late reports and corrections by respondents. All data are subject to revision 4 months after original publication.

[2] Prices for natural gas are lagged 1 month.

[3] Includes only domestic production.

[4] Most prices for refined petroleum products are lagged 1 month.

[5] Some prices for industrial chemicals are lagged 1 month.

r = revised.

22. Producer Price Indexes, for special commodity groupings

[1967 = 100 unless otherwise specified]

Commodity grouping	Annual average 1981	1981			1982									
		Oct.	Nov.	Dec.	Jan.	Feb.	Mar.	Apr.	May	June [1]	July	Aug.	Sept.	Oct.
All commodities — less farm products	295.7	299.5	299.4	300.0	302.0	301.9	301.4	300.9	301.2	r302.2	304.1	304.3	303.9	304.7

r=revised.

PRODUCTIVITY DATA

Productivity data are compiled by the Bureau of Labor Statistics from establishment data and from estimates of compensation and output supplied by the U.S. Department of Commerce and the Federal Reserve Board.

Definitions

Output is the constant dollar gross domestic product produced in a given period. Indexes of **output per hour of labor input**, or labor productivity, measure the value of goods and services produced per hour of labor. **Compensation per hour** includes wages and salaries of employees plus employers' contributions for social insurance and private benefit plans. The data also include an estimate of wages, salaries, and supplementary payments for the self-employed, except for nonfinancial corporations, in which there are no self-employed. **Real compensation per hour** is compensation per hour adjusted by the Consumer Price Index for All Urban Consumers.

Unit labor cost measures the labor compensation cost required to produce one unit of output and is derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from the current dollar gross domestic product and dividing by output. In these tables, **unit nonlabor costs** contain all the components of unit nonlabor payments except unit profits. **Unit profits** include corporate profits and inventory valuation adjustments per unit of output.

The **implicit price deflator** is derived by dividing the current dollar estimate of gross product by the constant dollar estimate, making the deflator, in effect, a price index for gross product of the sector reported.

The use of the term "man hours" to identify the labor component of productivity and costs, in tables 26 through 29, has been discontinued. **Hours of all persons** is now used to describe the labor input of payroll workers, self-employed persons, and unpaid family workers. **Output per all-employee hour** is now used to describe labor productivity in nonfinancial corporations where there are no self-employed.

Notes on the data

In the business sector and the nonfarm business sector, the basis for the output measure employed in the computation of output per hour is Gross Domestic Product rather than Gross National Product. Computation of hours includes estimates of nonfarm and farm proprietor hours.

Output data are supplied by the Bureau of Economic Analysis, U.S. Department of Commerce, and the Federal Reserve Board. Quarterly manufacturing output indexes are adjusted by the Bureau of Labor Statistics to annual estimates of output (gross product originating) from the Bureau of Economic Analysis. Compensation and hours data are from the Bureau of Economic Analysis and the Bureau of Labor Statistics.

Beginning with the September 1982 issue of the *Review*, all of the productivity and cost measures contained in these tables are based on revised output and compensation measures released by the Bureau of Economic Analysis in July as part of the regular revision cycle of the National Income and Product Accounts. Measures of labor input have been revised to reflect results of the 1980 census, and seasonal factors have been recomputed for use in the preparation of quarterly measures. The word "private" is no longer being used as part of the series title of one of the two business sector measures prepared by BLS; no change has been made in the definition or content of the measures as a result of this change.

26. Annual indexes of productivity, hourly compensation, unit costs, and prices, selected years, 1950–81

WAGE AND COMPENSATION DATA

DATA FOR THE EMPLOYMENT COST INDEX are reported to the Bureau of Labor Statistics by a sample of 2,000 private nonfarm establishments and 750 State and local government units selected to represent total employment in those sectors. On average, each reporting unit provides wage and compensation information on five well-specified occupations.

Data on negotiated wage and benefit changes are obtained from contracts on file at the Bureau, direct contact with the parties, and secondary sources.

Definitions

The **Employment Cost Index** (ECI) is a quarterly measure of the average change in the cost of employing labor. The rate of total compensation, which comprises wages, salaries, and employer costs for employee benefits, is collected for workers performing specified tasks. Employment in each occupation is held constant over time for all series produced in the ECI, except those by region, bargaining status, and area. As a consequence, only changes in compensation are measured. Industry and occupational employment data from the 1970 Census of Population are used in deriving constant weights for the ECI. While holding total industry and occupational employment fixed, in the estimation of indexes by region, bargaining status, and area, the employment in those measures is allowed to vary over time in accord with changes in the sample. The rate of change (in percent) is available for wages and salaries, as well as for total compensation. Data are collected for the pay period including the 12th day of the survey months of March, June, September, and December. The statistics are neither annualized nor adjusted for seasonal influence.

Wages and salaries consist of earnings before payroll deductions, excluding premium pay for overtime, work on weekends and holidays, and shift differentials. Production bonuses, incentive earnings, commissions, and cost-of-living adjustments are included; nonproduction bonuses are included with other supplemental pay items in the benefits category; and payments-in-kind, free room and board, and tips are excluded. *Benefits* include supplemental pay, insurance, retirement and savings plans, and hours-related and legally required benefits.

Data on negotiated wage changes apply to private nonfarm industry collective bargaining agreements covering 1,000 workers or more. Data on compensation changes apply only to those agreements covering 5,000 workers or more. *First-year* wage or compensation changes refer to average negotiated changes for workers covered by settlements reached in the period and implemented within the first 12 months after the effective date of the agreement. *Changes over the life of the agreement* refer to all adjustments specified in the contract, expressed as an average annual rate. These measures exclude wage changes that may occur under cost-of-living adjustment clauses, that are triggered by movements in the Consumer Price Index. *Wage-rate changes* are expressed as a percent of straight-time hourly earnings; *compensation changes* are expressed as a percent of total wages and benefits.

Effective wage adjustments reflect all negotiated changes implemented in the reference period, regardless of the settlement date. They include changes from settlements reached during the period, changes deferred from contracts negotiated in an earlier period, and cost-of-living adjustments. The data also reflect contracts providing for no wage adjustment in the period. Effective adjustments and each of their components are prorated over all workers in bargaining units with at least 1,000 workers.

Notes on the data

The Employment Cost Index data series began in the fourth quarter of 1975, with the quarterly percent change in wages and salaries in the private nonfarm sector. Data on employer costs for employee benefits were included in 1980, to produce a measure of the percent change in employers' cost for employees' total compensation. State and local government units were added to the ECI coverage in 1981, providing a measure of total compensation change in the civilian nonfarm economy.

Data for the broad white-collar, blue-collar, and service worker groups, and the manufacturing, nonmanufacturing, and service industry groups are presented in the ECI. Additional occupation and industry detail are provided for the wages and salaries component of total compensation in the private nonfarm sector. For State and local government units, additional industry detail is shown for both total compensation and its wages and salaries component.

Historical indexes (June 1981 = 100) of the quarterly rates of changes presented in the ECI are also available.

For a more detailed discussion of the ECI, see chapter 25, "The Employment Cost Index," of the BLS *Handbook of Methods* (Bulletin 1910), and the *Monthly Labor Review* articles: "Employment Cost Index: a measure of change in the 'price of labor,'" July 1975; "How benefits will be incorporated into the Employment Cost Index," January 1978; and "The Employment Cost Index: recent trends and expansion," May 1982.

Additional data for the ECI and other measures of wage and compensation changes appear in *Current Wage Developments*, a monthly periodical of the Bureau.

p = preliminary. r = revised.

34. Effective wage adjustments in collective bargaining units covering 1,000 workers or more, 1977 to date

Measure	Year					Year and quarter								
						1980		1981				1982^p		
	1977	1978	1979	1980	1981	III	IV	I	II	III	IV	I^r	II^r	III
Average percent adjustment (including no change):														
All industries	8.0	8.2	9.1	9.9	9.5	3.5	1.3	1.7	3.2	3.3	1.5	1.0	2.0	2.3
Manufacturing	8.4	8.6	9.6	10.2	9.4	2.9	1.7	2.3	2.4	3.1	1.9	.9	.9	1.6
Nonmanufacturing	7.6	7.9	8.8	9.7	9.5	4.0	1.1	1.2	3.8	3.4	1.1	1.0	2.7	2.8
From settlements reached in period	3.0	2.0	3.0	3.6	2.5	1.7	.5	.4	1.1	.5	.4	.2	.4	.5
Deferred from settlements reached in earlier period	3.2	3.7	3.0	3.5	3.8	1.2	.3	.5	1.4	1.5	.4	.5	1.4	1.2
From cost-of-living clauses	1.7	2.4	3.1	2.8	3.2	.7	.6	.7	.7	1.2	.6	.3	.2	.6
Total number of workers receiving wage change (in thousands)[1]	—	—	—	—	8,648	—	—	3,855	4,701	4,364	3,225	2,877	3,425	3,654
From settlements reached in period	—	—	—	—	2,270	—	—	579	909	540	804	203	493	588
Deferred from settlements reached in earlier period	—	—	—	—	6,267	—	—	888	2,055	3,023	882	1,006	1,627	2,379
From cost-of-living clauses	—	—	—	—	4,593	—	—	2,832	2,680	2,834	2,179	1,913	1,550	2,126
Number of workers receiving no adjustments (in thousands)	—	—	—	—	145	—	—	4,937	4,082	4,428	5,566	5,628	5,080	4,851

[1] The total number of workers who received adjustments does not equal the sum of workers that received each type of adjustment, because some workers received more than one type of adjustment during the period.

p=preliminary.
r= revised.

WORK STOPPAGE DATA

WORK STOPPAGES include all known strikes or lockouts involving 1,000 workers or more and lasting a full shift or longer. Data are based largely on newspaper accounts and cover all workers idle one shift or more in establishments directly involved in a stoppage. They do not measure the indirect or secondary effect on other establishments whose employees are idle owing to material or service shortages.

Estimates of days idle as a percent of estimated working time measures only the impact of larger strikes (1,000 workers or more). Formerly, these estimates measured the impact of strikes involving 6 workers or more; that is, the impact of virtually *all* strikes. Due to budget stringencies, collection of data on strikes involving 6 workers or more was discontinued with the December 1981 data.

35. Work stoppages involving 1,000 workers or more, 1947 to date

Month and year		Number of stoppages		Workers involved		Days idle	
		Beginning in month or year	In effect during month or year	Beginning in month or year (in thousands)	In effect during month (in thousands)	Number (in thousands)	Percent of estimated working time

MONTHLY LABOR REVIEW

Index of Volume 105
January 1982 through December 1982

INDEX OF VOLUME 105

JANUARY 1982 THROUGH DECEMBER 1982

ACCIDENTS (See Work injuries.)

AFL-CIO

The AFL and a national BLS: labor's role is crystallized, a centennial view. 1982 Mar. 21–29.

AGRICULTURE

The effects of the minimum wage on farm employment: a new model. 1982 June. 47–51.

Large supplies of meats, grains cut recent food price increases. 1982 Jan. 10–15.

Productivity growth average in farm machinery manufacturing. 1982 Oct. 6–10.

APPRENTICESHIP (See Education and training.)

ARBITRATION (See Collective bargaining.)

AUSTRALIA

Unemployment and labor force trends in 10 industrial nations: an update. 1982 Nov. 17–21.

AUTOMATION (See Technological change.)

BARGAINING (See Collective bargaining.)

BENEFITS (See Supplemental benefits.)

BUDGETS

Final report on family budgets: cost increases slowed, autumn 1981. 1982 July. 44–46.

Retired couple's budgets, final report, autumn 1981. 1982 Nov. 37–38.

BUREAU OF LABOR STATISTICS

The AFL and a national BLS: labor's role is crystallized, a centennial view. 1982 Mar. 21–29.

CANADA

Canadian legal approaches to sex equality in the workplace. 1982 Oct. 38–42.

Unemployment and labor force trends in 10 industrial nations: an update. 1982 Nov. 17–21.

CIVIL SERVANTS (See Public employees.)

COLLECTIVE BARGAINING

Easing the hardship of plant shutdowns. 1982 Mar. 43–44.

Organized labor in 1981: a shifting of priorities. 1982 Jan. 21–28.

CONFERENCES AND CONVENTIONS

Political issues dominate ILO conference; worker standards adopted. 1982 Oct. 35–38.

Thirty-Fourth Annual Meeting of the Industrial Relations Research Association, December 1981. Papers from. 1982 Apr. 47–51. 1982 May. 29–33. 1982 June. 45–54.

CONSTRUCTION

Labor and material requirements for hospital construction. 1982 Mar. 34–37.

CONSUMER PRICE INDEX

Changing the treatment of shelter costs for homeowners in the CPI. 1982 June. 9–14.

Inflation continues to abate during the first quarter. 1982 July. 3–9.

Reconciling the CPI and the PCE Deflator: an update. 1982 Jan. 43–44.

Reconciling the CPI and the PCE Deflator: 4th quarter 1981. 1982 May. 34–35.

Reconciling the CPI and the PCE Deflator: first quarter 1982. 1982 July. 37–38.

Reconciling the CPI and the PCE Deflator: second quarter 1982. 1982 Oct. 28–29.

COST OF LIVING

Cost-of-living indexes for Americans living abroad. 1982 Sept. 38.

Scheduled wage increases and cost-of-living provisions in 1982. 1982 Jan. 16–20.

CURRENT POPULATION SURVEY

Labor force data from CPS to undergo revision in January 1983. 1982 Nov. 3–6.

DISABILITY

Disability benefits for employees in private pension plans. 1982 Aug. 36–40.

DISCRIMINATION (See Equal Employment Opportunity.)

EARNINGS AND WAGES

General

Does a younger male labor force mean greater earnings inequality? 1982 Nov. 42–45.

Earnings gap. 1982 Nov. 2.

Earnings of men and women: a look at specific occupations. 1982 Apr. 25–31.

The effects of the minimum wage on farm employment: a new model. 1982 June. 47–51.

The Employment Cost Index: recent trends and expansion. 1982 May. 9–14.

Estimation procedures for the Employment Cost Index. 1982 May. 40–42.

New look at occupational wages within individual establishments. 1982 Nov. 22–28.
Occupational salary levels for white-collar workers, 1982. 1982 Oct. 30–32.
Pay equity emerges as a top labor issue in the 1980's. 1982 Apr. 49–51.
Public-sector union wage effects: a time series analysis. 1982 June. 51–53.
Scheduled wage increases and cost-of-living provisions in 1982. 1982 Jan. 16–20.
Tenure as a factor in the male-female earnings gap. 1982 Apr. 32–34.
The spendable earnings series: has it outlived its usefulness? 1982 Jan. 3–9.
Time rates tighten their grip on manufacturing industries. 1982 May. 15–22.
Unemployment and its effect on family income in 1980. 1982 Apr. 35–43.
Unpaid family workers: long-term decline continues. 1982 Oct. 3–5.
Usual weekly earnings: another look at intergroup differences and basic trends. 1982 Apr. 15–24.
Wage increases moderate in 1981. 1982 May. 3–8.
Weekly family earnings: a quarterly perspective. 1982 Aug. 46–49.
White-collar pay levels linked to corporate work force size. 1982 May. 23–28.
Why wages should not be blamed for the inflation problem. 1982 Apr. 44–45.
Work experience. 1982 Aug. 2.

Specified industries and occupations

Clerical pay differentials in metropolitan areas, 1961–80. 1982 July. 10–14.

ECONOMIC DEVELOPMENT AND GROWTH

The productivity puzzle: numbers alone won't solve it. 1982 Oct. 15–21.
Tracking job growth in private industry. 1982 Sept. 3–9.

EDUCATION AND TRAINING

Educational attainment of workers, March 1981. 1982 Apr. 52–55.
Human capital and multinationals: evidence from Brazil and Mexico. 1982 June. 45–47.

EMPLOYMENT (See also Unemployment; Labor force.)

Better measures of service employment goal of Bureau survey redesign. 1982 Nov. 7–16.
Blacks in the 1970's: did they scale the job ladder? 1982 June. 29–38.
Educational attainment of workers, March 1981. 1982 Apr. 52–55.
Employment problems and poverty: examining the linkages. 1982 June. 55–59.
Evaluating the 1980 projections of occupational employment. 1982 July. 22–30.
Labor force activity of women receiving child support or alimony. 1982 Nov. 39–41.
Labor force data: the impact of the 1980 census. 1982 July. 39–43.
Labor force patterns of students, graduates, and dropouts, 1981. 1982 Sept. 39–42.
Marital and family patterns of workers: an update. 1982 May. 53–56.
Occupational winners and losers: who they were during 1972–80. 1982 June. 18–28.
Shortages of machinists: an evaluation of the information. 1982 July. 31–36.
The employment situation in 1981: new recession takes its toll. 1982 Mar. 3–14.
The future of work: does it belong to us or to the robots? 1982 Sept. 10–14.
The Nation's employment situation worsens in the first half of 1982. 1982 Aug. 3–12.
Tracking youth joblessness: persistent or fleeting? 1982 Feb. 3–15.
Work experience. 1982 Aug. 2.

EQUAL EMPLOYMENT OPPORTUNITY

Canadian legal approaches to sex equality in the workplace. 1982 Oct. 38–42.
Labor Department's first program to assist black workers. 1982 June. 39–44.

EUROPE

Unemployment and labor force trends in 10 industrial nations: an update. 1982 Nov. 17–21.

EXPORTS (See Foreign trade.)

FEDERAL EMPLOYEES (See Public employees.)

FOREIGN TRADE

Imports and domestic employment: identifying affected industries. 1982 Aug. 13–26.
Import price indexes for crude petroleum. 1982 Nov. 29–32.

FRANCE

Unemployment and labor force trends in 10 industrial nations: an update. 1982 Nov. 17–21.

FRINGE BENEFITS (See Supplemental benefits.)

GOVERNMENT WORKERS (See Public employees.)

GREAT BRITAIN (See United Kingdom.)

HEALTH AND SAFETY (See Occupational safety and health.)

HEALTH INSURANCE PLANS

Determinants of health insurance and pension coverage. 1982 May. 30–32.

HOURS OF WORK

Productivity declined in 1980 in most industries measured. 1982 May. 36–39.
Workers on long schedules, single and multiple jobholders. 1982 May. 47–53.

HOUSING (See Construction.)

IMMIGRATION

Labor market rights of foreign-born workers. 1982 May. 32–33.
Select commission suggests changes in immigration policy—a review essay. 1982 Feb. 31–37.

IMPORTS (See Foreign trade.)

INCENTIVE PLANS

Time rates tighten their grip on manufacturing industries. 1982 May. 15–22.

INCOME (See Earnings and wages.)

INDEXES

Changing the treatment of shelter costs for homeowners in the CPI. 1982 June. 9–14.
Cost-of-living indexes for Americans living abroad. 1982 Sept. 38.
Employment Cost Index continues to decelerate in second quarter. 1982 Oct. 32–33.
Final report on family budgets: cost increases slowed, autumn 1981. 1982 July. 44–46.
Import price indexes for crude petroleum. 1982 Nov. 29–32.
Reconciling the CPI and the PCE Deflator: an update. 1982 Jan. 43–44.
Reconciling the CPI and the PCE Deflator: 4th quarter 1981. 1982 May. 34–35.
Reconciling the CPI and the PCE Deflator: first quarter 1982. 1982 July. 37–38.
Reconciling the CPI and the PCE Deflator: second quarter 1982. 1982 Oct. 28–29.
The Employment Cost Index: recent trends and expansion. 1982 May. 9–14.

INDUSTRIAL RELATIONS (See Labor-management relations.)

INDUSTRIAL RELATIONS RESEARCH ASSOCIATION

Thirty-Fourth Annual Meeting of the Industrial Relations Research Association, December 1981. Papers from. 1982 Apr. 47–51. 1982 May. 29–33. 1982 June. 45–54.

INFLATION (See also Prices.)

Inflation continues to abate during the first quarter. 1982 July. 3–9.
Price changes in 1981: widespread slowing of inflation. 1982 Apr. 3–14.
The spendable earnings series: has it outlived its usefulness? 1982 Jan. 3–9.
Why wages should not be blamed for the inflation problem. 1982 Apr. 44–45.

INJURIES (See Work injuries.)

INTERNATIONAL LABOR ORGANIZATION

Political issues dominate ILO conference; worker standards adopted. 1982 Oct. 35–38.

ITALY

Unemployment and labor force trends in 10 industrial nations: an update. 1982 Nov. 17–21.

JAPAN

Unemployment and labor force trends in 10 industrial nations: an update. 1982 Nov. 17–21.

JOB SATISFACTION

Did job satisfaction really drop during the 1970's? 1982 Nov. 33–36.

JOB VACANCIES

Labor turnover in manufacturing: the survey in retrospect. 1982 June. 15–17.
Shortages of machinists: an evaluation of the information. 1982 July. 31–36.

LABOR COSTS (See Unit labor cost.)

LABOR AND ECONOMIC HISTORY

Labor Department's first program to assist black workers. 1982 June. 39–44.
The AFL and a national BLS: labor's role is crystallized, A centennial view. 1982 Mar. 21–29.

LABOR FORCE

Does a younger male labor force mean greater earnings inequality? 1982 Nov. 42–45.
Educational attainment of workers, March 1981. 1982 Apr. 52–55.
Employment problems and poverty: examining the linkages. 1982 June. 55–59.
How accurate were projections of the 1980 labor force? 1982 July. 15–21.
How women's health affects labor force attachment. 1982 Apr. 56–59.
Jobs for college grads. 1982 Sept. 2.
Labor force activity of women receiving child support or alimony. 1982 Nov. 39–41.
Labor force data from CPS to undergo revision in January 1983. 1982 Nov. 3–6.
Labor force data: the impact of the 1980 census. 1982 July. 39–43.
Labor force patterns of students, graduates, and dropouts, 1981. 1982 Sept. 39–42.
Labor market rights of foreign-born workers. 1982 May. 32–33.
Marital and family patterns of workers: an update. 1982 May. 53–56.
More than half of all children have working mothers. 1982 Feb. 41–43.
Native Americans in the labor force: hunting for an accurate measure. 1982 July. 47–51.
New worklife estimates reflect changing profile of labor force. 1982 Mar. 15–20.
Occupational winners and losers: who they were during 1972–80. 1982 June. 18–28.
Shortages of machinists: an evaluation of the information. 1982 July. 31–36.
Sweden combats unemployment of young and older workers. 1982 Oct. 22–27.
The aging of the older population and the effect on its labor force rates. 1982 Sept. 27–29.
The employment situation in 1981: new recession takes its toll. 1982 Mar. 3–14.
The Nation's employment situation worsens in the first half of 1982. 1982 Aug. 3–12.
Tracking youth joblessness: persistent or fleeting? 1982 Feb. 3–15.
Unemployment and labor force trends in 10 industrial nations: an update. 1982 Nov. 17–21.
Unpaid family workers: long-term decline continues. 1982 Oct. 3–5.
Up and down. 1982 June. 2.
Work force reductions. 1982 July. 2.

LABOR LAW

State labor legislation enacted in 1981. 1982 Jan. 29–42.
Unemployment insurance laws: changes enacted during 1981. 1982 Feb. 16–23.

LABOR-MANAGEMENT RELATIONS

A model for measuring effectiveness of the grievance process. 1982 Apr. 47–49.
Can the NLRB caseload detect changes in labor relations climate? 1982 May. 29–30.
Easing the hardship of plant shutdowns. 1982 Mar. 43–44.
Helping labor and management see and solve problems. 1982 Sept. 15–20.
How European unions cope with new technology. 1982 Sept. 36–38.
Organized labor in 1981: a shifting of priorities. 1982 Jan. 21–28.

LABOR MARKET

Area labor market response to national unemployment patterns. 1982 Jan. 45–49.
GAO study focuses on problems of teenagers in labor market. 1982 Oct. 33–34.
Shortages of machinists: an evaluation of the information. 1982 July. 31–36.
Tracking job growth in private industry. 1982 Sept. 3–9.

LABOR ORGANIZATIONS

Becoming a union leader: the path to local office. 1982 Feb. 44–46.
Determinants of voter participation in union certification elections. 1982 Apr. 45–47.
Organizations of working women can pave the way for unions. 1982 June. 53–54.
Public-sector union wage effects: a time series analysis. 1982 June. 51–53.

LABOR REQUIREMENTS

Labor and material requirements for hospital construction. 1982 Mar. 34–37.
Labor market rights of foreign-born workers. 1982 May. 32–33.
Unemployment insurance laws: changes enacted during 1981. 1982 Feb. 16–23.

MANUFACTURING

Hand and edge tool industry experiences slow rise in productivity. 1982 Oct. 11–14.
Imports and domestic employment: identifying affected industries. 1982 Aug. 13–26.
Labor turnover in manufacturing: the survey in retrospect. 1982 June. 15–17.
Millwork industry shows slow growth in productivity. 1982 Sept. 21–26.
Nonwool yarn mills experience slow gains in productivity. 1982 Mar. 30–33.
Productivity growth average in farm machinery manufacturing. 1982 Oct. 6–10.
Time rates tighten their grip on manufacturing industries. 1982 May. 15–22.

MEDIATION

Helping labor and management see and solve problems. 1982 Sept. 15–20.

MINORITY WORKERS

Blacks in the 1970's: did they scale the job ladder? 1982 June. 29–38.
Labor Department's first program to assist black workers. 1982 June. 39–44.

MOBILITY

Blacks in the 1970's: did they scale the job ladder? 1982 June. 29–38.
Occupational changes and tenure, 1981. 1982 Sept. 29–33.

MULTIPLE JOBHOLDERS

Workers on long schedules, single and multiple jobholders. 1982 May. 47–53.

NATIONAL LABOR RELATIONS BOARD

Can the NLRB caseload detect changes in labor relations climate? 1982 May. 29–30.
Determinants of voter participation in union certification elections. 1982 Apr. 45–47.

NETHERLANDS, THE

Unemployment and labor force trends in 10 industrial nations: an update. 1982 Nov. 17–21.

OCCUPATIONAL SAFETY AND HEALTH (See also Work injuries.)

Another look at the link between work injuries and job experience. 1982 Feb. 38–40.
Job safety. 1982 Jan. 2; 1982 Dec. 2.
How valid are estimates of occupational illness? 1982 Aug. 27–35.
How women's health affects labor force attachment. 1982 Apr. 56–59.

OCCUPATIONS

Blacks in the 1970's: Did they scale the job ladder? 1982 June. 29–38.
Evaluating the 1980 projections of occupational employment. 1982 July. 22–30.
Occupational winners and losers: who they were during 1972–80. 1982 June. 18–28.
Shortages of machinists: an evaluation of the information. 1982 July. 31–36.

OLDER WORKERS

The aging of the older population and the effect on its labor force rates. 1982 Sept. 27–29.

PENSIONS (See also Supplemental benefits.)

Determinants of health insurance and pension coverage. 1982 May. 30–32.
Disability benefits for employees in private pension plans. 1982 Aug. 36–40.

PLANT SHUTDOWNS

Easing the hardship of plant shutdowns. 1982 Mar. 43–44.

POLAND

Solidarity's proposals for reforming Poland's economy. 1982 May. 43–46.

POPULATION

Select commission suggests changes in immigration policy—a review essay. 1982 Feb. 31–37.

POVERTY

An overview of the population below the poverty level. 1982 Aug. 53.
Economic hardship. 1982 Mar. 2.
Employment problems and poverty: examining the linkages. 1982 June. 55–59.

PRICES

Import price indexes for crude petroleum. 1982 Nov. 29–32.
Inflation continues to abate during the first quarter. 1982 July. 3–9.
Large supplies of meats, grains cut recent food price increases. 1982 Jan. 10–15.
Price changes in 1981: widespread slowing of inflation. 1982 Apr. 3–14.
Reconciling the CPI and the PCE Deflator: an update. 1982 Jan. 43–44.
Reconciling the CPI and the PCE Deflator: 4th quarter 1981. 1982 May. 34–35.
Reconciling the CPI and the PCE Deflator: first quarter 1982. 1982 July. 37–38.
Reconciling the CPI and the PCE Deflator: second quarter 1982. 1982 Oct. 28–29.

PRODUCTIVITY

Business studies views of managers and workers on productivity and quality. 1982 Apr. 58–59.
Cosmetics industry achieves long-term productivity gains. 1982 Dec. 28–32.
Hand and edge tool industry experiences slow rise in productivity. 1982 Oct. 11–14.
Impact of new electronic technology. 1982 Mar. 37–39.
International trends in productivity and labor costs. 1982 Dec. 3–14.
Labor and material requirements for hospital construction. 1982 Mar. 34–37.
Measuring productivity in service industries. 1982 June. 3–8.
Millwork industry shows slow growth in productivity. 1982 Sept. 21–26.
Nonwool yarn mills experience slow gains in productivity. 1982 Mar. 30–33.
Productivity declined in 1980 in most industries measured. 1982 May. 36–39.
Productivity growth average in farm machinery manufacturing. 1982 Oct. 6–10.
Productivity in commercial banking: computers spur the advance. 1982 Dec. 19–27.
Productivity increased in 1981 in most industries measured. 1982 Dec. 15–18.
Productivity in the pump and compressor industry. 1982 Dec. 38–45.
The office furniture industry: patterns in productivity. 1982 Dec. 33–37.
The productivity puzzle: numbers alone won't solve it. 1982 Oct. 15–21.

PROJECTIONS

Evaluating the 1980 projections of occupational employment. 1982 July. 22–30.
How accurate were projections of the 1980 labor force? 1982 July. 15–21.

PUBLIC EMPLOYEES

Analysis of work stoppages in the Federal sector, 1962–81. 1982 Aug. 49–53.
Public-sector union wage effects: a time series analysis. 1982 June. 51–53.

QUIT RATE

Labor turnover in manufacturing: the survey in retrospect. 1982 June. 15–17.

SAFETY (See Health and safety.)

SALARIES (See Earnings and wages.)

STATE GOVERNMENT

State labor legislation enacted in 1981. 1982 Jan. 29–42.
Unemployment insurance laws: changes enacted during 1981. 1982 Feb. 16–23.
Workers' compensation: key legislation in 1981. 1982 Feb. 24–30.

STATISTICAL PROGRAMS AND METHODS

Better measures of service employment goal of Bureau survey redesign. 1982 Nov. 7–16.
Forgotten unemployment: recall bias in retrospective data. 1982 Mar. 40–43.
How valid are estimates of occupational illness? 1982 Aug. 27–35.
Labor force data from CPS to undergo revision in January 1983. 1982 Nov. 3–6.
Native Americans in the labor force: hunting for an accurate measure. 1982 July. 47–51.

SUPPLEMENTAL BENEFITS

Bureau of Labor Statistics takes a new look at employee benefits. 1982 Aug. 41–45.
Workers' compensation: key legislation in 1981. 1982 Feb. 24–30.

SWEDEN

Sweden combats unemployment of young and older workers. 1982 Oct. 22–27.
Unemployment and labor force trends in 10 industrial nations: an update. 1982 Nov. 17–21.

TECHNOLOGICAL CHANGE

How European unions cope with new technology. 1982 Sept. 36–38.
Impact of new electronic technology. 1982 Mar. 37–39.
New technology. 1982 May. 2.
The future of work: does it belong to us or to the robots? 1982 Sept. 10–14.

TENURE

Job tenure of workers in January 1981. 1982 Sept. 34–36.
Occupational changes and tenure, 1981. 1982 Sept. 29–33.
Tenure as a factor in the male-female earnings gap. 1982 Apr. 32–34.

TRADE UNIONS (See Labor organizations.)

TRAINING (See Education and training.)

UNEMPLOYMENT (See also Employment; Labor force.)

Area labor market response to national unemployment patterns. 1982 Jan. 45–49.
Forgotten unemployment: recall bias in retrospective data. 1982 Mar. 40–43.
GAO study focuses on problems of teenagers in labor market. 1982 Oct. 33–34.
The employment situation in 1981: new recession takes its toll. 1982 Mar. 3–14.
Sweden combats unemployment of young and older workers. 1982 Oct. 22–27.
Tracking youth joblessness: persistent or fleeting? 1982 Feb. 3–15.
Unemployment and its effect on family income in 1980. 1982 Apr. 35–43.
Unemployment and labor force trends in 10 industrial nations: an update. 1982 Nov. 17–21.
Work force reductions. 1982 July. 2.

UNEMPLOYMENT INSURANCE

Unemployment insurance laws: changes enacted during 1981. 1982 Feb. 16–23.

UNION MEMBERSHIP AND ELECTIONS

Determinants of voter participation in union certification elections. 1982 Apr. 45–47.
Becoming a union leader: the path to local office. 1982 Feb. 44–46.

UNIONS (See Labor organizations.)

UNIT LABOR COST

International trends in productivity and labor costs. 1982 Dec. 3–14.
Labor and material requirements for hospital construction. 1982 Mar. 34–37.

UNITED KINGDOM

Unemployment and labor force trends in 10 industrial nations: an update. 1982 Nov. 17–21.

WAGES (See Earnings and wages.)

WEST GERMANY

Unemployment and labor force trends in 10 industrial nations: an update. 1982 Nov. 17–21.

WHITE-COLLAR WORKERS

Occupational salary levels for white-collar workers, 1982. 1982 Oct. 30–32.
White-collar pay levels linked to corporate work force size. 1982 May. 23–28.

WHOLESALE PRICE INDEX (See Prices; Indexes.)

WOMEN

How women's health affects labor force attachment. 1982 Apr. 56–59.
Labor force activity of women receiving child support or alimony. 1982 Nov. 39–41.
More than half of all children have working mothers. 1982 Feb. 41–43.
Organizations of working women can pave the way for unions. 1982 June. 53–54.
Pay equity emerges as a top labor issue in the 1980's. 1982 Apr. 49–51.
Tenure as a factor in the male-female earnings gap. 1982 Apr. 32–34.
Up and down. 1982 June. 2.

WORK INJURIES AND ILLNESSES

Another look at the link between work injuries and job experience. 1982 Feb. 38–40.
How valid are estimates of occupational illness? 1982 Aug. 27–35.
Job safety. 1982 Jan. 2; 1982 Dec. 2.
Occupational deaths declined in 1980, BLS survey finds. 1982 Jan. 49–52.

WORKLIFE

New worklife estimates reflect changing profile of labor force. 1982 Mar. 15–20.

WORK STOPPAGES

Analysis of work stoppages in the Federal sector, 1962–81. 1982 Aug. 49–53.

WORKERS' COMPENSATION

Workers' compensation: key legislation in 1981. 1982 Feb. 24–30.

YOUTH (See Labor force.)

DEPARTMENTS

BLS Bulletins

National Survey of Professional, Administrative, Technical, and Clerical Pay, March 1982. Bulletin 2145, 80 pp., $4.75 (GPO Stock No. 029-001-02720-6). Summarizes results of the Bureau's annual survey of selected white-collar occupations in private industry. Results are used for a number of purposes, including general economic analysis and age and salary administration by private and public employers. One important use is to provide the basis for setting Federal white-collar salaries under the provisions of the Federal Pay Comparability Act of 1970.

Relative Importance of Components in the Consumer Price Indexes, 1981. Bulletin 2141, 35 pp., $4.50 (GPO Stock No. 029-001-02716-8). Presents data on the expenditure or value weights of components in the Consumer Price Indexes, expressed as a percentage of all items. The data can be used in conjunction with the *CPI Detailed Report.*

Area Wage Survey Bulletins

These bulletins cover office, professional, technical, maintenance, custodial, and material movement occupations in major metropolitan areas. The annual series of 70 is available by subscription for $90 per year. Individual area bulletins are also available separately.

Baltimore, Maryland, Metropolitan Area, August 1982. Bulletin 3015-39, 40 pp., $4.50 (GPO Stock No. 029-001-90160-7).

Chattanooga, Tennessee-Georgia, Metropolitan Area, September 1982. Bulletin 3015-43, 28 pp., $3.50 (GPO Stock No. 029-001-90164-0).

Greensboro-Winston-Salem-High Point, North Carolina, Metropolitan Area, August 1982. Bulletin 3015-42, 30 pp., $3.75 (GPO Stock No. 029-001-90163-1).

Fresno, California, Metropolitan Area, June 1982. Bulletin 3015-38, 25 pp., $3.50 (GPO Stock No. 029-001-90158-5).

Nassau-Suffolk, New York, Metropolitan Area, August 1982. Bulletin 3015-40, 35 pp., $4.50 (GPO Stock No. 029-001-90161-5).

Northeast Pennsylvania Metropolitan Area, August 1982. Bulletin 3015-41, 41 pp., $4.50 (GPO Stock No. 029-001-901162-3).

Industry Wage Survey Bulletins

These studies include results from the latest BLS survey of wages and supplemental benefits, with detailed occupational data for the Nation, regions, and selected areas (where available). Data are useful for wage and salary administration, union contract negotiation, arbitration, and Government policy considerations.

Savings and Loan Associations, February 1980. Bulletin 2106, 73 pp., $5 (GPO Stock No. 029-001-02718-4).

Structural Clay Products, September 1980. Bulletin 2139, 61 pp., $5 (GPO Stock No. 029-001-02719-4).

Union Wages and Benefits Bulletin

Printing Trades, September 1980. Bulletin 2125, 152 pp., $6.50 (GPO Stock No. 029-001-02717-6). The final publication in a series of BLS bulletins reporting on union wage rates, benefits, and weekly straight-time hours for specified crafts or jobs as provided in labor-management agreements in five industries. Other industries in the series are construction, grocery stores, local transit, and local trucking. These studies have now been discontinued because of budget constraints.

Periodicals

CPI Detailed Report. August issue provides a comprehensive report on price movements for the month, questions and answers on upcoming changes in the measurement of homeownership costs, statistical tables, charts, and technical notes. 109 pp., $5 ($28 per year).

What does it cost to live abroad?

Many firms need to know so they can adjust the pay of their American employees stationed abroad. The answer now is available by subscription to this quarterly publication, issued by the Bureau of Labor Statistics of the U.S. Department of Labor. The indexes are based on the difference between living costs in Washington, D.C., and each of more than 160 foreign cities. Each issue also lists U.S. State Department housing (quarters) allowances for about half of the cities and hardship differentials for all important posts.
